We are now told that the bumper crops are to lift the cloud which hangs over the industries of the country and times are to be better. They seem to forget that bumper crops result in lower prices, and thus the farmer does not get much more money for what he sells and he will have substantially no more money with which to buy, especially under a tariff law which takes off practically all protection on agricultural crops.

No use talking, the Hon. Bumper Crop is a great educator. We can easily remember when such a crop was attributed, by the party in power, to their "wise statesmanship." In those days we never were told the truth, which was that a "bumper crop" gave every handler except the farmer better pay for his labor. If Mr. Payne and his friends were wise they would hardly admit this fact about the bumper crop. What is to prevent some critical farmer from asking this question: "If what you say is true, what have you been doing for the past 20 years to make the conditions which bump the farmer in this way. What do you offer as a remedy now?" There is the point in the entire discussion. It is not a question of producing more or selling more, but it is a question of handling and distributing farm products so that the producer will receive a larger share of the consumer's dollar. We hope the Hon. Bumper Crop will hold his pupils in school until they go through with the problem, and tell us how to increase that 35-cent dollar.

BREVITIES.

GIVE attention to the colt's feet.

Is there anyone left who thinks spraying does not pay a fruit grower?

NO—demanding interest on your money is not the highest principal of life.

THE "June bug" crop is reported heavy in Wisconsin This means a pest of white grubs next season. They can be partly cleaned out by Fall-plowing old meadows and clearing up brush and trash.

THE West Virginia Experiment Station will help farmers locate local deposits of lime. It is claimed that every county of the State contains lime ledges, while nine-tenths of the unproductive land is deficient in humus and lime.

THE Florists' Exchange tells of a swindler who recently cleared about $2,000 by selling four-leaved clover seed to hopeful Californians. The purchasers probably begin to doubt the efficiency of lucky signs.

IN Ontario, Canada, there is more than enough good land to support several times the present population. The government is paying money to induce foreigners to come in and take up land, while the present rural population is going to town to live! Here is a double problem which comes to every community after the pioneer generation.

A BUSHEL OF POTATOES AND WHAT HAPPENED TO IT.

THE quantity of potatoes involved in this story was something over 800 bushels, but for simplicity's sake we have taken a bushel as the unit. The question therefore, that we are setting out to answer is: What happened to this bushel, which represents the average of the 800 bushels involved?

The total cost of producing the bushel of potatoes was, omitting small fractions, 43 cents. The various items that entered into this 43 cents were as follows: Seed, eight cents; fertilizer, 20 cents; plowing, six mills; planting, two and two-fifths cents; cultivating, one and three-fifths cents; spraying, six and two-fifths cents; harvesting and sacking, four cents. The yield was at the rate of 125 bushels to the acre. The potatoes had to be hauled from the farm to the station, a distance of about a mile; shipped by rail a distance of 16 miles, then hauled from the station in the city to the commission man one mile. The cost of freight and drayage at both ends was seven cents, bringing the total cost of the bushel of potatoes to 50 cents.

The potatoes were sold by the commission man, who made returns for each shipment, but as a matter of fact it was definitely known that in some cases where the returns were made the potatoes had not actually been sold. The commission man allowed, as is the practice with commission men in some places, what he considered a fair price for the potatoes. In this particular case it was 60 cents, after his commission of five cents per bushel had been taken out. Thus, after we had actually paid out 50 cents in the production of the crop, had spent four months in growing it, had taken the risks of drought, insects, fungus diseases, and so forth, we had a profit of 10 cents per bushel.

As a matter of interest, we followed certain shipments of these potatoes which, while they may not fully represent the average, so nearly is this the case that the results are worthy of note. It was found that certain of the shipments upon which returns had been made at 60 cents a bushel were actually being sold to jobbers for one dollar per bushel, or three dollars per barrel. The jobbers in turn sold the potatoes to certain retailers at an advance of 25 cents per bushel. The retailers, who were men running small stores in the city, were retailing these same potatoes to their customers in small quantities at 10 cents a quarter of a peck, or at the rate of 40 cents a peck or $1.60 per bushel.

Here, then, is a difference in price between the producer and the consumer of one dollar per bushel; or, in other words, the crop after it leaves the grower's hands suddenly takes on a value of 40 cents per bushel to the commission man; 25 cents to the jobber, and 35 cents to the retailer.

Putting it in another way, the grower, after four months' effort, realized a profit on his investment of 20 per cent.; the commission man, who acted in the dual capacity of commission man and wholesaler, after holding the product an average of 48 hours, realized a profit of sixty-six and two-thirds per cent.; the jobber, on a short turn-over, 25 per cent., and the retailer, on an average holding of probably three days, 28 per cent.

These are statements of fact which in a more or less degree will be found to apply to nearly all of the perishable crops that the farmer produces. We make no comment at this time, being content with pointing out the necessity of organized, intelligent effort to bring the producer and the consumer a little closer together.

B. T. GALLOWAY.

New York State News.

COUNTY HIGHWAY SUPERINTENDENTS.—The semi-annual convention of county highway superintendents was held June 25 at Ithaca. There were about 400 present, the largest attendance in the history of the organization. Senator Geo. A. Blauvelt was one of the speakers. He remarked that too much time and money was spent on the elimination of grades and the construction of perfectly straight roads. He said that the highways already built cannot be maintained out of the appropriations made annually by the Legislature. Dr. E. Haskell was another speaker, and the superintendents generally entered into the informal discussions. A trip through the county for road inspection was made.

APPLE SPECIAL.—It is stated that the New York Central Railroad will run an "apple special" after the State Fair through the fruit sections of Western New York. The company will collect data showing the prices per barrel or box of all the principal grades of apples grown in that section, at every month of the year that apples are marketed, and comparisons will be made with prices in various cities. The data will cover 20 years. These data will be placed on a large chart and exhibited in one of the cars, and another chart will show the acreage of bearing orchards and the number of young trees set within the last five or ten years. It is expected that the figures will show that there is a smaller acreage in orchards now than there was 10 years ago.

$50,000 WORTH OF CHEESE.—The statement of the fact that on June 27 the sales of cheese on the Watertown Produce Exchange amounted to 10,385 boxes at 13½ and 13⅝ cents per pound, means little to the casual reader. But its real meaning is that for the 380,000 pounds of cheese sold the sum of $50,000 will be paid to the farmers of Jefferson County. A year ago the sales amounted to 11,160 boxes, at 14 to 14⅛ cents. At Gouverneur it is no uncommon thing to see of a Monday forenoon 30 to 40 teams loaded with 30 to 40 cheese each, averaging about 70 pounds, awaiting shipment. The shipments from January 1 to June 22 amounted to 12,930 boxes, weighing 985,000 pounds.

THE CANNERIES.—The canning plants in Wayne County are opening up for business; in fact, have already done considerable on peas and strawberries. One company has been canning from 2,000 to 2,500 quarts of strawberries daily. Spinach is also being tinned at Sodus. This crop is said to net the grower $20 per ton. It is put up in gallon tins.

CROP CONDITIONS.—According to the crop reports of the Department of Agriculture of this State, the large apple-growing counties of tthe Western part of the State will produce twice as many apples as last year, of the Winter varieties; but the Hudson Valley crop will be somewhat lighter. Outside the commercial apple-growing sections the apple crop will be notably smaller owing largely to the ravages of insects. Taking 100 as the maximum for the crop of 1913, all grains but wheat and barley rank this year from 101 to 116.

INSECTS IN APPLE BELT.—Late reports from the apple belt are to the effect that growers are showing considerable concern over the insect damage, owing to the dry weather of the first three weeks of the month. In Niagara County it is reported that the aphis is doing much injury. In Monroe County it is said that some of the finest orchards have been threatened by the fruit tree leaf roller. Like reports come from Oneida County owing to neglect in fighting the Codling moth and canker worm.

J. W. D.

Conditions in Ashtabula County, Ohio.

THERE will be no peaches in Northeastern Ohio along the lake shore. The grapes are setting well, and promise to be a better crop than last year. Strawberries were from one-half to two-thirds crop. This was due to dry weather the latter part of May and the first part of June. Some late strawberry patches yielded well after the appearance of rain the middle of June. Cherries are a fair crop, yet last year there were four times as many as this year. There will be but few apples, and scarcely any pears. Plums are almost a failure. The dry weather injured the hay crop. Rains which came the 18th of June gave the grass a fresh start. Many farmers were starting cutting their hay at this time. In Denmark township, where a large amount of hay is cut each year, this year the hay crop will be about 85 per cent. for the locality, while in other sections it will be only about 60 per cent. There is practically no hay left over.

Cheese factories paid for the month of May, hauling to be deducted, $1.08 to $1.12, the Ohio & Pittsburg Milk Company $1.23, hauling to be deducted, and the Rick factory at Jefferson $1.36, with bonus for high-testing milk. There seems to be more milk produced in the county this year than any other year for a decade. The manager of the factory at Leon declared that last year the total amount of milk produced in their territory and going to their and other factories and shippers totaled but half the amount received by them alone when they first invaded the territory ten years ago. This is due to many farmers from Western Ohio buying the dairy farms, and specializing more in crops and corn, and with a few hogs, than previously when dairy cows were kept. Many of the low-producing dairies and dairy cows have been sold, which reduces the cost of the milk. Milk inspection has had a tendency to improve the quality of milk, for one of the inspectors advises the farmers that he proposes to encourage them to produce better milk at a profit, rather than discourage the average farmer by insisting that he should comply with rigid inspection. There are more new barns being built and more barns remodeled than any two years heretofore. The number of silos to be erected this year will be one-third more than last year, which was a record year.

The acreage of rye planted last Fall was twice that of any previous year, and the crop looks good in all sections of the county. There is a larger acreage of wheat than in previous years, and it will be ready for cutting about July 5th. Oats were planted late, three-fourths of the acreage of the county having been planted between May 20th and June 1st. A larger part of the corn was planted after June 1st. Oats will be a fair crop, while corn promises to be good. Farmers are raising about one-third more calves to replenish their dairies than heretofore. Cows are selling around $60 and $70, veal calves are bringing eight cents at the farm, eggs about 17 cents, and butter 17 to 20 cents at the local stores. These prices are much lower than last year. Seed potatoes scarce at 50 cents, and eating potatoes are 75 cents and $1.00. There is more available farm help this Summer than at any time heretofore, yet there seems to be a shortage of efficient farm labor.

Farm machinery sales are greater than heretofore in the history of the county. There are more riding plows of the single bottom type being sold this year than heretofore. Three good heavy horses are used on the plows and the farmers are practicing deep plowing. Horses are selling from $160 to $225. The sale was pretty lively among farmers when Spring work opened, but at present sales are quiet. There is but little demand for drivers, and only the serviceable farm horses, from 1,200 pounds upward, are in demand. There were one-third more colts foaled this year than previous years. These are practically all draft bred. One owner states that he has recorded only 17 services to his trotting-bred stallion, while a nearby Percheron owner has booked about 100 mares. Real estate is moving slowly, farms are selling from $40 to $60 an acre in the interior of the county, while along the lake shore sales are quite lively, with farms bringing from $100 to $300 and even higher, depending on the condition, the amount of fruit and location. Bees have not done as well as in former years, according to several bee keepers, owing to the late, cold Spring, and a good many bee keepers and farmers report one-third of their swarms having been lost during the Winter. This year there will be no bee inspection in Ashtabula County. All the apiaries have been found in former inspections to be in healthy condition, and those which were infected with foul brood were put in healthy condition by the introduction of Italian queens, in compliance with the State Department.

There are between 40 and 50 dairies operated by the milking machine, and double this number of plants will be in operation before the present season is past, is the opinion of several dairymen. Three years ago was a banner corn year, and this year promises to produce nearly as good corn.

WALTER JACK.

New Jersey Crops Encouraging.

THE following report as to New Jersey crops is made from the summary of replies received by the State Board of Agriculture from the first call for crop information this Summer. Rain seems to have been abundant in the northern counties, while in the southern the drought has been very severe, causing a 50 per cent. reduction in the strawberry crop, a severe injury to early market garden crops. Asparagus is marked at 50 per cent. of a full yield, and there is a heavy reduction in the yield of grass for hay and pasture.

Atlantic County states: "Very hot and dry; no rain for six week."

Salem County reports: "No rain; so much corn has failed to germinate. Asparagus is the only market garden crop. Some beds have cut well, but the price has been lower. Other beds have not cut more than 50 per cent. Hay is not more than one-half a crop. Many farmers have not been able to plow their grounds for late tomatoes. No rain for about seven weeks."

Cape May: "Late, cold Spring; very dry now and unfavorable weather in general for any crop except peas for canning and late corn. Some few people are harvesting a fine yield of grass, while others are complaining of a very short crop."

Monmouth: "Potatoes looking extra fine. Ten per cent. increase in acreage over last year."

Union: "Unfavorable weather conditions and crops so backward as to give no prospects at this date for any reliable crop estimates. No planting of any amount done in this locality until May 18. Corn not all planted to date; nights too cold and weather conditions unfavorable for growth. The strawberry crop will be about one-half of what was expected two weeks ago. Season and crop conditions about four weeks behind."

Passaic: "The hay crop will be very good, season having been very favorable."

Morris rejoices as follows: "Crops never looked better at this time of season, with the exception of corn, which is not quite as forward as some other years. Present indications for hay were never better. Potatoes are unusually fine, with enough rain to mature the crop. Altogether the farmer's outlook is very encouraging. Alfalfa is not grown very extensively. Only a few have tried it to date."

Burlington: "Potato acreage about 10 per cent. less than formerly. A five weeks' drought is working havoc on many crops. Conditions were favorable for large crops generally until the present dry spell began. Unless relief comes soon most truck crops will be very light."

Somerset: "The prospect for fruit is said to be excellent. Wheat is very poor, owing to the fly and the wonderful growth of Timothy, which has choked the grain. Some will mow their harvest fields for hay. What we need most is rain."

Conditions whether favorable or unfavorable, as indicated by ten reports received, are: Corn, nine replies favorable; wheat, four favorable, four unfavorable; potatoes and market garden crops, favorable by counties. Seven report favorable on peaches and apples. Since the reports from which this summary is made were written a copious rain has visited Gloucester and other southern counties, which will help all unmatured crops. The general condition of the cranberry plantations is favorable for a good crop.

D. T. H.

Government Cotton Report.

THE Bureau of Statistics estimates the condition at the close of June as 79.6 per cent. of normal. This is an advance of 4.3 per cent. over one month previous, and 2.2 under last year. Acreage and percentages by States follow:

States.	Planted 1914.	
Virginia	46,000	86
North Carolina	1,589,000	82
South Carolina	2,826,000	81
Georgia	5,398,000	83
Florida	194,000	..
Alabama	3,912,000	88
Mississippi	3,148,000	81
Louisiana	1,389,000	81
Texas	12,052,000	74
Arkansas	2,527,000	80
Tennessee	866,000	79
Missouri	124,000	93
Oklahoma	2,854,000	79
California	35,000	..

Other Cotton Experts.

Jay, Boud & Co. estimate the crop at 77.7 of normal, with the following detailed percentages: North Carolina, 77.3; South Carolina, 77.3; Georgia, 82.3; Florida, 81.8; Alabama, 83.5; Mississippi, 84.5; Louisiana, 83.5; Texas, 72.1; Arkansas, 77.7; Tennessee, 81.6; Missouri, 85.3; Oklahoma, 75.6; various, 87.0.

A Norden & Co.'s estimate is 80.1, with these details: North Carolina, 78; South Carolina, 79; Georgia, 83; Alabama, 89; Mississippi, 80; Louisiana, 80; Texas, 77; Oklahoma, 80; Arkansas, 79; Tennessee, 82.

Other percentages given without details are: Clement, Curtis & Co.: 75.8. National Ginners' Association, 78.3. R. M. Giles, 79.

Kansas Grain Crops.

Secretary F. D. Coburn reports the Kansas wheat crop as 154,000,000 bushels, on an area of 8,873,000 acres. This is 60,000,000 bushels greater than any previous Kansas wheat yield. The condition of corn is 93.8 per cent., or 8.2 more than last year. About 5,500,000 acres are planted. There are 1,470,000 acres in oats; condition 87.1, or 37.8 better than a year ago.

Woman and the Home

From Day to Day

Too Late.

What silences we keep year after year
With those who are most near to us, and dear!
We live beside each other, day by day,
And speak of myriad things, but seldom say
The full sweet word that lies just in our reach,
Beneath the commonplace of common speech.

Then out of sight and out of reach they go,
Those close, familiar friends, that loved us so;
And sitting in the shadow they have left,
Alone with loneliness and sore bereft,
We think with fond regret of some fond word
That once we might have said and they have heard.

For weak and poor the love that we expressed
Now seems beside the vast, sweet, unexpressed,
And slight the deeds we did, to those undone,
And small the service spent to treasure won,
And undeserved the praise for word and deed
That should have overflowed the simple need.

This is the cruel cross of life—to be
Full-visioned when the ministry
Of death has been fulfilled, and in the place
Of some dear presence is but empty space.
What recollected services can then
Give consolation for the "might have been"? —Nora Perry.

*

JAPANNED trays which become dull with use should be washed with lukewarm water and white soap, then rinsed and dried with a soft towel. A little sweet oil on a soft cloth polishes them.

*

SEVERAL of our readers have told us of local clubs or societies that have brightened the social life of their district. Many of the old-time pleasures of the country have passed away, because they were associated with the industrial conditions of their period. In too many cases it seems as though few new pleasures have taken their place. There are many agencies now employed in bettering the conditions of rural life, but we think that the real impetus must come from the farm family itself, and this depends, first of all, on improved economic conditions. We should like to hear of any rural clubs or associations that are enlivening the social life, or otherwise increasing the pleasures of the country. The experience of one locality is often very interesting to another.

*

THE Federal Bureau of Education is now searching for American versions of old English and Scotch ballads, which were brought to this country by the early settlers. Prof. C. Alphonso Smith of the University of Virginia is to conduct the search. Modern conditions of life, and the vogue of popular songs, often trivial in character, have displaced these old ballads, which are often remarkable for simplicity, vigor of narrative, and intensity of feeling. Among the songs of this class which are being looked for are Barbara Allen, The Wife of Usher's Well, The Beggar Laddie, Johnny Armstrong, etc. It is most likely that early American forms of these ballads will be found among Southern mountaineers, in districts where there has been little or no foreign immigration for many generations.

*

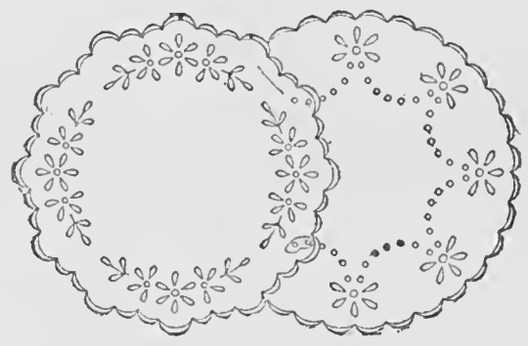
RIBS of beef in Spanish style is a savory method of cooking the ends of a rib roast, which are usually overcooked and still not tender, when roasted with the rest of the joint. Fry some of the beef fat in the bottom of a large cooking kettle, then slowly cook in this one large onion sliced and half a green pepper free from seeds. Draw the onion and pepper to one side of the pan when slightly colored, and brown the top and cut edges of the meat in the fat, until browned all over. Before this browning the meat should be wiped, sprinkled with pepper and salt, and dredged with flour. Then, leave the meat in the kettle, with the onion and pepper, add one cup of water and one cup of sliced tomato. Cover closely and cook slowly until the meat is very tender, adding more water if needed. When ready to serve, take out the meat, skim off the fat, and thicken with a little flour, letting the gravy boil up for five minutes to thicken. The same method of cooking is good for any of the cheaper cuts of meat, such as chuck or neck of mutton; the long slow cooking in the closed vessel makes it tender and develops excellence of flavor.

The Rural Patterns.

When ordering patterns always give number of patterns and measurement desired. Price of each pattern 10 cents.

8280A. Boy's Norfolk suit. Cut in sizes 4 to 10 years. Size 8 years requires

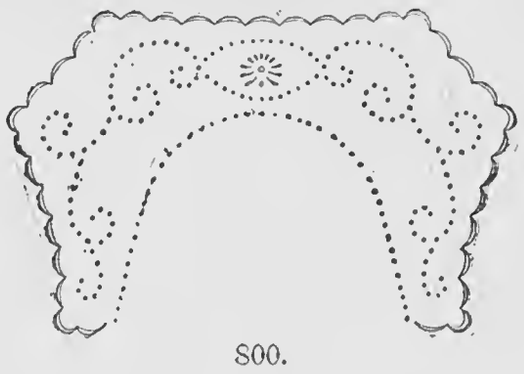
three yards of 36 material. 8270A, Girl's loose cost. Cut in sizes 8 to 14 years. Size 12 years requires three yards of 36 inch material. 8272, Misses' loose coat. Cut in sizes 16 and 18 years. Size 16 years requires 3⅝ yards of 36 inch material with one-half yard 27 inches for collar and cuffs. 8233, Girls' one-piece dress. Cut in sizes 6 to 10 years. Size



817.

8 years requires 2¼ yards of 36 inch material, with five-eighths yard of 27 inches for trimming. 8274A, Girl's dress. Cut in sizes 6 to 10 years. Size 8 years requires 2⅝ yards of 36 inch material.

No. 817. Designs for embroidering two nine-inch doylies. The scalloped edges are designed to be padded and buttonholed; the sprays of leaves to be worked



800.

either in solid embroidery or as eyelets; the stems are to be outlined, and the dots made as eyelets or in solid work. Stamped on best Scotch linen with mercerized floss to work, for the two 30 cents.

Set of six of each design $1.70.

No. 800. Design for embroidering a fancy collar. The scalloped edge is designed to be padded and buttonholed, the dots can be worked solidly, in satin stitch, or as eyelets. The figure at the back is designed for solid work.

Stamped on pure Irish linen with floss to work, 25 cents.

Seen in New York Shops.

A PRETTY hat for a litle girl was made of white dotted swiss; it had a large puffed crown and drooping brim which was lined with pink silk. Around the crown was a twist of white taffeta ribbon with a pink picot edge, the spreading bow at one side extending down on to the brim. This is a pretty style for a child when trimmed with pink, blue or pale yellow.

Smocking makes a desirable trimming for children's dresses, and is often used on those of a better class. A plain little dress of Alice blue chambray was almost as simple in cut as the old-time farmers' smock, and had in back and front, a narrow yoks of smocking with a double row of white crochet buttons down the center. Round collar and turn-back cuffs of white linen were finished with a picot edge of Irish crochet, and this was the only trimming.

Velvet hats were naturally scheduled to appear with the warm sticky days of mid-June. Among the first were some with black velvet crowns and white straw brims, but these were quickly followed by shapes entirely covered with velvet, both black and white. White velvet hats were especially displayed for the international polo match. One black velvet hat noted was a small sailor shape, trimmed with six white Gardenias, put around the crown half way up, and a fold of white satin at the base of the crown. It was $7.50. Another was trimmed with four small white wings, set irregularly at front, back and sides.

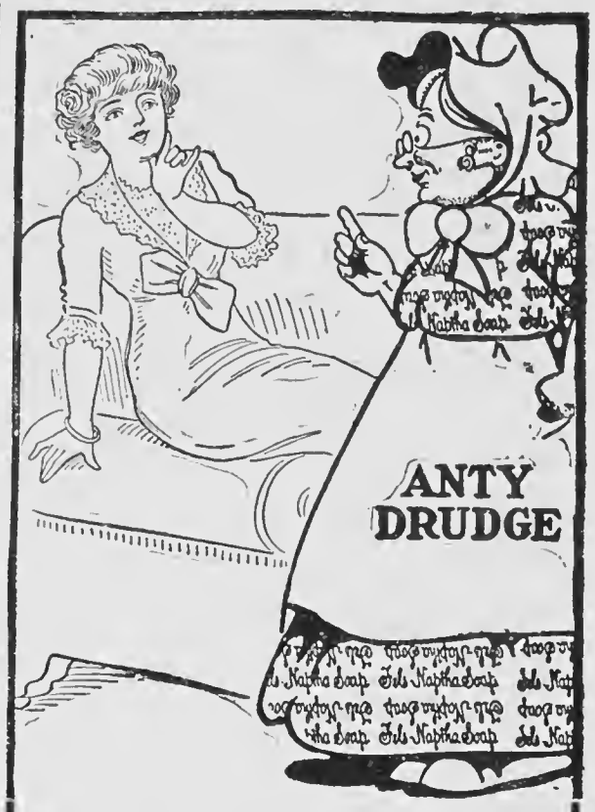
Bathing caps begin at 25 cents and go up to many dollars. There are really pretty caps at 50 cents, made of soft rubber cloth in a variety of colors, red, blue, green, etc.; they are mob-cap shape. A little higher are smart turbans, consisting of a close cap underneath, with a fold of the material that is twisted around the head and fastened with a snap fastener. The more expensive ones are made of rubberized satin to match the bathing suit. The cheaper bathing shoes are made of a sort of drilling, but better ones are of black satin, "tango" style, with cross laces that pass through eyelets in the high back; they cost $1.50. Some of the new bathing suits have plain drawers coming to the knee or just below, with a little skirt short enough to show about six inches of the drawers.

Tight-fitting basques buttoned all down the front are promised us with the Fall styles. Some already seen are what used to be called French or Gabrielle basques, fitted in the front by a long curving seam from the shoulder, instead of darts; they look just like the basques worn when Mrs. Rutherford B. Hayes presided over the White House; some are even edged with side-pleatings, the sleeves being finished in the same way. It is said that we shall see separate basques worn with odd skirts, a fashion that will be very helpful to women of small incomes. Why not? We have been wearing separate shirt waists ever since basques "went out."

"Shadow-proof" petticoats, offered for wearing under thin Summer dresses, are made of white pique or cotton poplin. They follow the narrow lines of the dress skirt, and, have no trimming except a frill of four-inch embroidery set on the lower edge. The waist line is faced, having no band, and it is closed with snap fasteners, there being no fullness at the top. Some very pretty ones are brocaded piqué. After seeing the radiograph effect produced by one thin muslin petticoat under a scant Summer gown one realizes the value of these opaque materials. More expensive ones are of white French percale of opaque quality, edged with hand-worked scallops.

Of course children are wearing capes, like their elders, and a favorite model is a circular shape with a hood, the regular Little Red Riding-hood type. A very pretty one was rose-colored corduroy lined with white china silk. Cotton corduroy, which comes in many colors and under many names, is suitable for these capes, also basket cloth, which is often quite inexpensive.

The law condemns the man or woman
Who steals the goose from off the common;
But lets the greater felon loose
Who steals the common from the goose.
—London Opinion.



Mrs. Gay—"Anty Drudge, I'm just delighted with Fels-Naptha Soap. My washing is all done without a bit of steam or smell, and it's such a comfort to know I've gotten rid of the sickening odor of boiling clothes. I use it for John's flannels, too. It leaves them so soft and white."

Anty Drudge—"My dear, you are the third who has said that to me this morning. I'm certainly glad I told you about Fels-Naptha Soap."

You *used* to have to boil your clothes to get them clean, but nowadays progressive women all over the country use Fels-Naptha Soap. Their clothes are clean and their work is done in half the time it used to take.

Fels-Naptha works best in cool or lukewarm water, without hard rubbing or boiling. It is especially good for woolens because hard rubbing ruins them, and Fels-Naptha does away with all hard rubbing.

Buy it by the carton or box and follow directions on the Red and Green Wrapper.

Fels & Co., Philadelphia.

FELS-NAPTHA

"Best Yet" Lemon Pie.

I HAVE for years used a recipe, obtained from your paper, and called "best yet" lemon pie, but I have recently lost it and would like very much to get another copy of it. M. O. H.

This recipe was sent us in 1908 by Margaret Cavanaugh Daly, and has given great satisfaction. Beat together one cupful of sugar, one level tablespoonful of flour, juice and grated rind of one lemon, yolks of three eggs. Just before putting the filling in the crust add one and one-fourth cup of fresh milk. Bake carefully and not too long. Beat the whites stiff, add one-third cupful of sugar, cover pie with this meringue, and brown lightly in the oven.

Tomato Recipes.

WILL you give some different ways of using tomatoes? MRS. S. P.

We have given many ways of using tomatoes, but will repeat some of them, and add others, avoiding the familiar ones that "every woman knows."

Tomato Conserve.—This may be called condensed tomato sauce; it is sold by Italian grocers, and put up by Italian housekeepers, who use it in all sorts of cooking where tomato is desired. It may be diluted for sauce, added to soups and stews, etc. Put in an earthen stewpan as many sound ripe tomatoes as desired; cook over a very slow fire until the skin slides off; then strain through a hair sieve, pressing with a wooden spoon. Do not keep the first watery liquor that passes through the sieve. Replace in stewpan adding a dessertspoonful of mixed spice to each pound of tomatoes; salt to taste. Stir over a slow fire until very thick, then cool in an earthen basin. When cool put in wide-mouthed bottles, stand the bottles in a kettle of water, like any other preserves; boil for 15 minutes, then cool.

Italian Stuffed Tomatoes.—Required, six tomatoes, two ounces bread crumbs, one ounce cheese, four eggs, parsley. Cut the stem pieces off six tomatoes, remove cores and seeds and fill with the following mixture: Two ounces of bread crumbs soaked in vinegar and strained, one ounce grated cheese, two hard-boiled eggs finely chopped, a dessertspoonful finely chopped herbs (basil or savory), pepper and salt to taste. Mix well with two beaten eggs, and fill tomatoes with the mixture. Cover the top of each tomato with bread crumbs mixed with finely chopped parsley, put a small piece of butter on each, and put on a greased baking pan. Cook in a slow oven 20 minutes.

Panned Tomatoes.—These are excellent served with roast meats. Put in a pan with two ounces of butter six firm tomatoes that have been cut in halves. Cook slowly on the top of the range for 10 minutes, then brown quickly in the oven. Remove the tomatoes to a hot platter, and make a sauce by adding to the browned butter two tablespoonfuls of flour, and after it is rubbed smooth one pint of milk. Stir until boiling. Season well with salt and pepper and pour over the tomatoes. Garnish with parsley and points of toast.

Scallop of Tomatoes and Potatoes.—Season a pint of peeled and chopped tomatoes with salt, pepper and onion juice to suit the taste, and add enough potatoes to make a cupful when chopped fine. Butter a baking dish and sprinkle with bread crumbs and put in half of the tomatoes; then a layer of soft crackers, buttered and broken in coarse bits. Cover the crackers with two heaping tablespoonfuls of grated American cheese. Then add the remainder of the tomatoes, more cracker crumbs and bits of butter and place in a hot oven. Bake 20 minutes. Serve at once.

Fried Green Tomatoes.—Cut both stem and blossom end from large green tomatoes, cut in thin slices, roll in flour, and fry in hot butter. Sprinkle with salt, pepper and a little sugar, and cook until brown. A little onion may be fried with them if desired.

Tomatoes and Cheese.—Cut the stem end from large ripe tomatoes, and with a small spoon scoop out the inside. To each two tablespoonfuls of the pulp add one teaspoonful of bread crumbs and the same amount of cheese crumbled fine. Season, fill the tomatoes with this mixture, replace the stem ends, and bake for 20 minutes. Tomatoes may be stuffed with green corn, boiled rice, chopped meat or macaroni, and many tasty dishes may be made in this way.

Creamed Tomatoes.—Cut ripe tomatoes in thick slices, fry until tender in hot butter, and then set on a hot platter in the open oven. Stir a tablespoonful of flour into the butter in the pan, let it cook till well blended, and then stir in a cupful of milk in which a pinch of soda has been dissolved. Stir and cook to a smooth sauce, season and pour over the tomatoes. This may be varied by adding a teaspoonful of curry powder to the cream sauce.

Curried Tomatoes.—Put in the frying pan a heaping tablespoonful of butter and half a small onion, grated. Cook about two minutes, then stir in a scant teaspoonful of curry powder. Cut tomatoes in slices, fry brown in the seasoned butter, sprinkle with salt, and serve on a hot platter.

Cooling Drinks for Summer.

THE Summer drink should not only be daintily prepared, but attractively served; thin glasses, a pretty tray, or one neatly covered with a doily, straws with which to imbibe, a few flowers, and a plate of tempting sandwiches or dainty little cakes, are all pleasing and important accompaniment.

To make a delicious plain lemonade, wash and dry four large lemons. Cut them into halves, reserving four thin slices; squeeze the juice into a bowl, and strain; then add one cupful of sugar and four cupfuls of boiling water, and blend thoroughly. Cover closely, and allow it to stand until cold. Serve well iced, with one thin slice of lemon in each glass. Some like a dash of ginger or nutmeg added. Orangeade may be made in the same manner, with the exception of the juice of one-half lemon added to that of every four oranges, or if the oranges are tart a little less sugar. The water used boiling hot in the making of these drinks develops the fruit flavor far more deliciously than if used cold.

A delightful fruit punch is made by boiling three cupfuls of sugar, three pints of water, and the grated rind of three lemons and two oranges for eight minutes. In the meantime cook two cupfuls of grated pineapple in two pints of water for 20 minutes; then add the syrup and cool. When perfectly cold add one pint of raspberry or strawberry juice, with the juice of the three lemons and two oranges; blend well, and strain. Serve in tall glasses with cracked ice, and a thin slice of orange or a few tiny cubes of pineapple, added to each glass.

If one wishes a little nourishment in the form of cooling drink, iced chocolate, egg-nog, or any of the milk preparations are especially useful. A beaten egg added to a glass of lemon or orangeade not only improves it but makes it a nutritious drink.

Chocolate syrup is nice to have on hand as well as the lemon, make it in this way: Melt two squares of unsweetened chocolate with two tablespoonfuls of hot water, over hot water, then add two cupfuls of boiling water, and one cupful of sugar. Cook five minutes, add one tablespoonful of vanilla extract, strain, and bottle. Keep this also in a cool place until needed.

For a delicious egg-nog, particularly nice for children's lunches, beat the white and yolk of one egg separately, to the yolk add a speck of salt, and two teaspoonfuls of sugar, and one teaspoonful of crushed ice, and beat thoroughly; then add one cupful of ice-cold milk, three-fourths of the beaten white of egg, and one teaspoonful of vanilla. Mix well, and pour into glasses. Sweeten and flavor the remaining white of egg, and garnish the top with it. Egg-nog should be used at once after it is made, for the egg loses much of its freshness and lightness by being exposed to the air.

Kumiss is a beverage that can be enjoyed by the non-invalid as well as the invalid, it is partially predigested milk, containing carbonic acid and a little alcohol, both of which have a tonic effect. To prepare it: Dissolve one-fifth of a two-cent cake of compressed yeast in a little water and mix it with one quart of perfectly fresh milk, and one tablespoonful of sugar. Put the mixture into strong bottles—beer-bottles are best—cork tightly with well-fitting stoppers, and fasten down securely with a piece of picture wire or stout string. Shake the bottles well to mix the ingredients thoroughly, then place them on end in the ice-box, or some cool place, to ferment slowly. At the end of the third day lay the bottles on their sides, turning them occasionally. From four to five days is required to complete the fermentation; it is then ready for use. ROSAMOND LAMPMAN.

Tested and Tried.

Keep a pair of carpenter's clamps for use in the kitchen. By clamping the molding board to the end of your work table you may add much to the capacity of the table when baking is in progress. Use it also to clamp the ironing board to the table to avoid it slipping about; or the sleeve board to the larger board.

The leaky rubber water bottle may be made to do duty in an emergency by filling with hot salt. Fine gravel may be sifted and kept on hand for this purpose, either salt or gravel having the advantage over hot water that they retain the heat longer.

The funnel is a better egg separator than anything sold especially for the purpose because easier to clean. Break the egg carefully into the funnel, when the white will slip through leaving the yolk unbroken.

If you cannot get bitter oranges for your marmalade you may add to the bitter flavor of marmalade made from sweet oranges by the use of the seeds. Save both orange and lemon seeds when cutting up the fruit, cover with water and let stand overnight. This will develop into a jelly which, when added to the fruit, will greatly aid in the jellying process as well as add to the flavor of this imitation Scotch marmalade. M. E. S. H.

CANNED STRING BEANS.—Wash and cut the beans in inch pieces. Add water enough to cover, and to each quart of beans, add one teaspoonful cream of tartar. Boil 20 minutes and put in fruit cans. When using them pour off the water; rinse well in cold water. Cook in usual way, adding one teaspoonful baking soda to each quart of beans. This is a tested recipe and the beans are as nice as those that are boiled several hours in the cans. M. P.

To prove to you that it costs less money, takes less time, makes better food, to cook in

"Wear-Ever"
ALUMINUM UTENSILS

We wish to send this one-quart stewpan for only ten 2-cent stamps.

More than a quarter of a million women have tested "Wear-Ever" ware in this way.

"Wear-Ever" utensils save fuel because they get hot quickly and stay hot longer than any other kitchen ware.

They save work because in them your food bakes without turning the pan, boils without stirring, roasts without basting.

Replace utensils that wear out with utensils that "Wear-Ever"

Send for booklet, "The 'Wear-Ever' Kitchen" (free) which tells you how to improve your cooking and cut down expense.

WANTED: Men to demonstrate and sell "Wear-Ever" Specialties. Only those who can furnish security will be considered.

The Aluminum Cooking Utensil Co.
Dept. 53, New Kensington, Pa., or
Northern Aluminum Co., Ltd., Toronto, Ontario
Send prepaid 1-qt. "Wear-Ever" Stewpan. Enclosed is 20c. in stamps—money refunded if not satisfied.

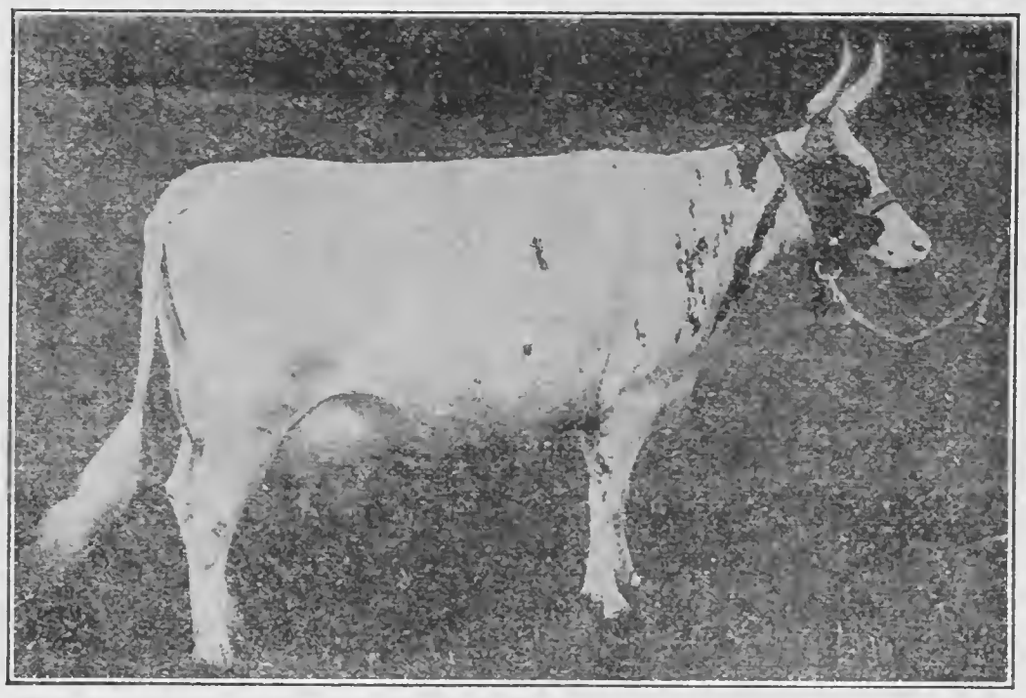
Live Stock and Dairy

SUCCEEDING WITH AYRSHIRE CATTLE.

[Read by E. J. Fletcher at the Farmers' Week Meeting at the Massachusetts Agricultural College.]

The Ayrshire breed is said by many to have originated from Channel Island breeds, and from white wild cattle of Scotland, but this the Scotchmen firmly deny. At any rate they originated in the county of Ayr, Scotland, and have been bred there for more than a century; the Ayrshire cow of today is a cow of medium size weighing from 1,000 pounds to 1,200, the bulls from 1,500 to 2,000 pounds.

The Ayrshire is a rather nervous cow and will use those nerves to support herself. They are always active in walking, eating, and chewing their cud, showing a nervous energy that should go well toward making milk. The first importation was made into the United States in 1822, the first into Massachusetts in 1837. At that time Ayrshires were little known, as no herd books had been published in this country or Scotland, but as the people become more acquainted with the breed and found them proving their worth as dairy animals, and becoming more interested in them, a herd book was established in Scotland in 1878, and in the U. S. in 1863. I think there were thirteen men to incorporate the Ayrshire Breeders' Association. I purchased my first Ayrshire animal, a bull four months old, about 22 years ago and



AYRSHIRE COW DALFIBBLE CRUMMIE IMP.

even went in debt for him. Afterwards when I asked the man I purchased him from, how he knew I would ever pay him, he replied: "If you knew enough to know you wanted Ayrshires I knew I was sure of my pay." I soon added more to my number, and as I bred and cared for them much myself, I became more and more interested in them, and always thought I would go to Scotland some day and see the Ayrshire in their native home.

Four years ago I had the great pleasure of doing so. While there I made a close study of the Scotchman's methods in caring for, breeding, and developing their animals. I found, too, that the women and girls look after the cattle as much as or more than the men, feeding and milking them, and they knew the pedigree of each animal as well as, if not better, than the men. In my estimation the Scotch people are the keenest and wisest breeders in the world, and have bred the Ayrshires almost to perfection. In the first place, his business is his life's ambition, and he watches it in every detail. His business is his pleasure, his theatre, his whole life's work, and some of the best Scotch breeders take more enjoyment in seeing the cattle they have developed look right, walk right, than we Americans at our various places of amusement, and satisfy their ambition in having such animals led out before them.

Mr. Osbone of Morton Mains, breeder of Nellie Osbone of Chicago World's Fair fame, had some of his animals led out before me, (his son was leading them out). One did not show just right, when his father said: "Alex, you ken better nor that, bring her back again." And Alex brought her back walking backwards holding her head well up and making her walk right. They will even spend a whole day at cattle shows, looking at the success of other breeders, and studying the way in which they can benefit themselves in their individual work. Let me say right here, the Scotchman, if he has an animal deficient in spring of rib, will feed cut hay and grain and spring those ribs out; if he has an animal with turned down horns he will put them in training and soon have them up where they will have a more attractive look. They will say the Ayrshire cow has everything, but is apt to have short teats. That has been carefully watched in this country and today I can show you whole herds, large herds, all with good teats, as good as any of the dairy breeds.

The Ayrshire cow has inherited a strong constitution and great dairy capacity, that fits her to endure the changes of our New England climate and to produce a large quantity of dairy products at the lowest cost. For example of this our Champion Ayrshire cow produced 23022 pounds milk at a cost of .0159 per quart; 1080 pounds butter. Our best four-year-old 17657 pounds milk, 966 pounds butter. Our best three-year-olds 14582 pounds milk, 754 pounds butter; 15122 pounds milk, 631 pounds butter; 15056 pounds milk; 693 pounds butter. Our best two-year-old 12773 pounds milk, 626 pounds butter. Our best 10 cows average 18737 pounds milk, 971 pounds butter; 419 entries mature class 10531 pounds milk, 479 pounds butter. 146 four-year-olds, 9599 pounds milk, 446 pounds butter; 179 three-year-olds, 8950 pounds milk, 415 pounds butter; 351 two-year-olds, 7866 pounds milk, 373 pounds butter; 1112 all classes, 9378 pounds milk, 435 pounds butter. Years ago when I won second in the home dairy test with a cow giving 10701 pounds milk and 506 pounds butter, it was considered a good record, but today the whole class going into advanced registry average nearly that, and more than our best records 15 years ago, showing the rapid advancement the Ayrshire breed has made in this very short period of time.

At the present time, with limited capital, I would advise a man to buy a purebred sire, always remembering that a sire is half the herd, study his breeding, become acquainted with him in every particular. Find out what his dam has done, also his grand-dam, see what the females have done on his sire's side, as a purebred sire is stronger blooded than a grade, you will get his blood stronger in your herd. If you buy a bull from a cow giving 30 pounds of milk a day and breed him to a herd of 30 pounds, how can you expect the results of better than a 30-pound cow? Buy a bull from a 60-pound cow and your breeding should be a 45-pound cow; a bull from a 30-pound cow bred to a 60-pound cow would most likely put you back to a 45-pound cow or less. We claim a good bull half the herd. A good cow may breed for 12 or 14 years, and if you get six or seven heifer calves you are lucky, but a good bull will leave that number from a small herd in one year, so you can see his worth. A bull should be tried and kept until you can see what his progeny can do; if an improvement over their dams you have started right; then purchase a few choice females. It is better to have a small number of choice animals than a large number of animals of inferior quality.

Success is bound to follow such careful study and thoughtful breeding. Watch the other man to see what he is doing to profit by another's success or failure; find out what to do to keep up with the procession. The breeder must not stay at home satisfied with his own doings, but go out among the other breeders, looking over their animals to see how they compare with his; join the clubs with the men breeding Ayrshires, and they will help you a whole lot in advancing. I think showing at fairs helps you by comparing your animals with the other man's. It also helps you to advertise. I remember the first time I showed I won first on bull and a first on a female and I thought all I had to do was breed them and raise prize winners forever. After showing your stock at fairs you are apt to sell some stock, and you want to sell to make a success. Become interested in all your customers, study their herds, and see where you can help them as much as possible, as you must remember that any good record they may make will help you as well as themselves. Help them to sales if possible, as that gives them more encouragement, and as they make sales you will find them making more purchases and telling their friends of their success, and more buyers follow.

You will sell many animals on description, and always try to describe them as nearly as they are as possible, so as not to disappoint the buyer. You must be a good care-taker, as care means profit, and your herd must have good care in order that you can have animals that will not disappoint the buyer. A man told me once if you can stand before a pen of calves, chew a straw and watch them grow and you enjoy it you will be a success. I like to see the many changes a calf from a few days old will make until it becomes mature. They are very interesting. Now after you have made some sales you feel you are getting back some of your first cost. I know I felt better over my first sale, a bull calf at $25, than I did years later when I sold a cow for $1,000. A farmer in New England cannot afford to keep poor stock. If he wants purebreds, he should choose the breed he likes the best and stick to it; he will never make a success of a breed he does not like, no matter how good it is.

Owned Her Foal Through Fright.

SEEING the question asked by A. R., page 822, reminds me of an experience we had, several years ago, with a mare, who would not own her foal. After several weeks of watching her constantly, to prevent injuring the foal, she became a little less vicious, and we turned her out, for a little while, to graze. The first day she was out, we forgot all about her, and there came up a severe thunderstorm. As soon as it passed we made haste to find the mare and foal. The storm had accomplished what we had found impossible. Whether it was fright, or the thorough ducking the foal had received in the storm I cannot say. We had no more trouble, as the mare owned it ever after, or till weaned. She had several foals and always owned them, with this one exception. I do not say this is a sure way to induce the mare to care for her foal, but it might be tried, under certain conditions, that are obvious, and if successful, would save considerable work, and a much better foal would result. Save Your Sheep

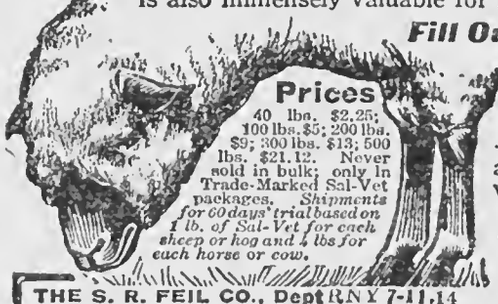
I'll Stop Your Worm Losses

Don't let your sheep or lambs sicken and die from worms. I'll stop your losses from stomach and intestinal worms—I'll prove it or no pay. Henry L. Wardwell, the great Shropshire Breeder says: "We use Sal-Vet as a preventive of worms, and keep it before our sheep at all times, on pasture, and in the barn."

Sidney R. Feil Pres.

The Great Worm Destroyer **SAL-VET** The Great Live Stock Conditioner

is regarded as the "salvation of the sheep business," by many breeders. It is also immensely valuable for hogs, horses and cattle.



Prices 40 lbs. $2.25; 100 lbs. $5; 200 lbs. $9; 300 lbs. $13; 500 lbs. $21.12. Never sold in bulk; only in Trade-Marked Sal-Vet packages. *Shipments for 60 days' trial based on 1 lb. of Sal-Vet for each sheep or hog and 4 lbs for each horse or cow.*

Fill Out the Coupon Below

Tell me how many head of stock you have, and I'll ship you enough Sal-Vet to last them 60 days. You pay the freight on arrival—feed as directed, and if it does not do all I claim, I'll cancel the charge—you won't owe me a penny.

Bloated Stock.

I SEE, on page 842, directions for tapping a bloated animal, by A. S. Alexander, M. D. C. I think I have a better and quicker cure for cattle than tapping. About 30 years ago a farmer told me if I ever had a bloated cow to get hold of the tongue and hold it out one side of the mouth. I never had any cattle to bloat until three years ago. Then I had a calf which was very bad. I took hold of the tongue and held it for about 15 minutes and the gas came out and gave instant relief. Then I gave a dose of Epsom salts and it was entirely cured. Last year I had a cow and cured her the same way. I told one of my neighbors, and last Fall he had a cow that was bloated very badly. He tried my cure and he said it worked to perfection. By holding the tongue out it lets the gas escape. You can fairly see it. You can cure a cow while you are getting ready to tap it. Of course it might not always work, but it has for me, and I have told all of my neighbors, as I think it is something everyone who has cattle should know, especially if raising Alfalfa or Red clover.

New Jersey. ELLIS TIGER.

Feeding Little Turkeys.

MRS. E. J. RIDER and Mrs. Grover tell how they raise turkeys and what they feed young turkeys. What kind of "pudding" do they make and how do they make it? I have a good number, they hatch well and are of good stock, and I would like to get the best results in raising them. J. B.

The first few years of my experience with turkeys I fed bread and milk and hard boiled egg with lots of black pepper. Results were not very satisfactory and finally I read of someone who fed wheat bran and sour milk. I resolved to try it, and did so with excellent success. Wheat bran is a bulky food, but will not pack and harden in the bowels, and the lactic acid of the sour milk is medicinal in that it kills any germs along the digestive tract. Turkeys in the wild state rear their young in the woods, and they must subsist almost entirely on insects for the first few weeks. In domestication they are more or less confined, and where there are so many to consume the insects on a small area it does not supply meat food enough for their needs. The most natural and easily digested meat food we can supply is raw egg.

The little turkeys are left in the nest two days or as long as the mother will sit quietly. From the nest they are put in a roomy coop having a detached floor, and given grit or fine sand or sifted oyster shells, and clean water. After two hours mix together about one pint wheat bran, one raw egg and enough sour milk to make a crumbly mash, and feed a few spoonfuls on a clean board. Grit in some form and clean water are kept before them, and the mash given four times a day. Never overfeed. Take out the board and any food left as soon as they are satisfied.

One Spring I took off a brood in April. It was still quite cold and wet and a snow squall visited us in a few days. I thought surely my poults would die, and I loaded their food with ginger and black pepper to keep them warm. I was not disappointed, most of them did die, but it was pepper and not cold that killed them. It set me thinking, and it looked only reasonable that the tender little stomachs could not stand such medicine. Now I give it only in case of sickness, and then red pepper, which is an aid to digestion.

In case of a wet spell I cover the front of coop with pieces of oil cloth, old rubber coats or whatever is at hand to keep out the rain; be sure they have dry bed and keep them in until rain is over. My coops are all made of good tight boards or matched lumber, painted and with back and top covered with roofing paper. Coal ashes are excellent to dry a wet coop. Everything must be clean as possible around turkeys. If free to choose their own quarters they will roost in a clean place always. Coop should be lifted from the floors and cleaned every other day, sometimes floors scalded and coops whitewashed. Drinking dishes and feeding boards should also be scalded.

The bran-sour-milk-egg mixture is the only food given for three or four weeks. Then very gradually, giving only once a day at first, work them onto oat flake and a good brand of fine chick feed. Cracked wheat and a little cracked corn are good and much relished. Continue the bran and sour milk once a day until cold weather, and give them any good grain such as wheat, buckwheat, oats, barley and corn, or better still a mixture, feeding only morning and night. Be sure they have plenty of grit and clean pure water, never letting them drink from a stagnant pool. One thing which greatly helps little poults is greens cut very fine with the scissors and mixed with other feed. Sour milk, which is too old and has become rancid of course cannot be fed, and I much prefer it uncooked, giving whey and all. Also be sure you are feeding a good grade of bran, preferably Winter bran, or what is commonly known as mixed feed, and good grains of all kinds, which are not sour or musty or false. Do not confine them too long in coop or yard, let them exercise, but keep from wet grass. There are many things in favor of this method of feeding. Bran and sour milk are both very inexpensive. Clear eggs tested from the incubator are as good as any; it is easily prepared and gives best results. I have not had a case of diarrhœa or leg weakness and no drooping wings since feeding this way and my turkeys have grown fine large frames, weighing heavier than ever before. I never feed puddings, johnny cake or other cooked food. Cornmeal can be added to the mash after poults are half grown.

MRS. NILES GROVER.

I feed my turkeys good sweet bread and milk until they are old enough to eat wheat, good wheat, not screenings. I feed the wheat until they are full grown. As they grow older I mix cracked corn with the wheat. Keep clean, fresh water where they can get it at all times. See that they do not get lousy. I scarcely ever lose a poult, only by accident. The wheat makes bone and muscle and keeps them growing. You may say wheat is expensive, so also is it to lose your poults.

MRS. E. J. RYDER.

White Diarrhœa and Germs.

I FEEL I must write you after reading the article on white diarrhœa in a recent issue. The author, like myself, was informed that germs did the work. Now I always get hot under the collar when these germ theories are advanced in the poultry business. I have been through epidemics of both white diarrhœa and roup, and have always tried to dig down and find the real fundamental cause of any trouble with my fowls, and I have proved to my own satisfaction that fowls kept under proper conditions and properly fed and bred are immune to these two diseases, which I used to consider the scourge of the poultry business. Now, instead of hunting for some germ with name a mile long, I have hunted for causes I was able to correct. I find by raising my chicks under hens I have entirely eliminated white diarrhœa, and by cutting out all meat and forcing foods I have entirely stopped roup, and hemorrhage of the spleen. This latter trouble used to take lots of hens in the Spring, and is a trouble you never read about, and I would never have found out what the trouble was had I not dissected the dead hens. U. D. SYDNOR.

Virginia.

I have had many arguments of this type put up to me. In the first place, did Mr. Sydnor's chickens have bacillary white diarrhœa, and would he know it if they had it; or did they have just plain bowel trouble caused by poor feeding, management, etc.? If it was plain bowel trouble caused by poor feeding, etc., going back to the old hen would in most cases stop the trouble, as it did with Mr. Sydnor's chicks. On the other hand if they had bacillary white diarrhœa (a germ disease that is in most cases inherited from the mother) as he claims, and understands artificial incubation and brooding, the difference either way in mortality between natural and artificial raised chicks would be too small to consider a factor. I feel sure Mr. Sydnor's chicks had some bowel or other trouble caused by poor feeding and management, and not bacillary white diarrhœa. If going back to natural incubation and brooding would cure this disease as Mr. Sydnor claims, why are all the leading experiment stations spending so much time on this disease?

Roup is another germ disease, and usually follows a cold in damp and badly ventilated houses, and in houses and yards that are not sanitary. Hens that are well fed and kept in properly ventilated, clean and dry houses, under sanitary conditions can in almost all cases by nature throw off or resist the germs of roup. The chances are Mr. Sydnor forced his hens by over-feeding meat and other forcing feeds until they were broken down or weak. In this condition they could not overcome or resist the germs of roup or colds, especially if the weather had been cold and wet, and the houses damp. EDWARD S. PARSONS.

CALVES AND SOUR MILK.—The Department of Agriculture reports experiments in feeding sour milk to calves: "Sour skim-milk was fed to 22 calves, Holsteins, Jerseys and Guernseys, at different seasons of the year. In no case did it cause digestive disturbances even when the change from sweet to sour milk was made abruptly when the calves were only a few days old. Moreover, no evil results followed the alternate use of sweet and sour. It seems, therefore, that the common idea that sour milk leads to scours is quite unfounded. The calves, it was found, did not like the sour milk as well as the sweet, but in the majority of cases soon became accustomed to it. The aversion, however, increased when the milk was fed them at a low temperature."

DOCTOR: "Well, Mr. McPherson, I'm glad to see you out again. You've had a long illness." McPherson: "Ay, Doctor, and verra expensive. I was wonderin' if it was worth while at ma time o' life."—Punch.

Notice to Cow Owners

U. S. Agricultural Department recommended Sterile Air for the Treatment of Milk Fever. Send and get one of Dr Myers Sterile Air Milk Fever Outfits. The only outfit made with a bulb for cleansing after using. Directions with outfit. Price, $3.00. Ex. paid. C. H. MYERS, D. V. S., 100 Berlin St., Middletown, Conn.

Pinehurst Shropshires

Best Breeding flock in America. Foundation stock for sale. Send for illustrated catalogue to H. L. WARDWELL
Box E Springfield Center, N. Y.

DAIRY CATTLE

FOR SALE—Registered Ayrshires of quality. A small herd consisting of cows, yearlings and heifer calves, headed by a son of Bargenoch Victor Hugo. Will sell as a herd or singly. A. F. Curtis, Ballardvale, Mass.

Holstein Calves—3 to 5 weeks old, 15-16ths pure, well marked, $20 each, crated for shipment anywhere. Edgewood Farm, Whitewater, Wis.

YOUNG REGISTERED HOLSTEIN BULL

127791, now ready for sale. Well bred, handsome individual, even black and white. $135. We have two others more fashionably bred and higher priced. MOHEGAN FARM, Hudson Valley Headquarters for Purebred Stock. CHAS. H. BAKER, Owner, Peekskill, New York

BARGAIN SALE HOLSTEIN BULL

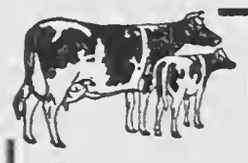
ready for heavy service; son of the Great Milk and Butter King; A. R. O. dam. Two choice cows due in August. Several male calves. One fine heifer calf. HILLHURST FARM, F. H. Rivenburgh, Prop., Munnsville, N. Y.

East River Grade Holstein Cows For Sale

100 cows served to calve in August, September and October, all served to registered bulls. STRICTLY DAIRY TYPE AND GUARANTEED. 60 yearling heifers. 40 two-year old heifers all sired by pure blooded bulls from high producing dams. 10 extra well-bred registered bulls, PONTIAC BREEDING, from A. R. O. DAMS. If you are looking for extra good dairy cows, visit the EAST RIVER HOLSTEINS. Special price for the next 30 days. WE TUBERCULIN TEST. JOHN B. WEBSTER, Dept. Y, Cortland, N. Y. Bell Phone 14, F.5.

HIGH GRADE HOLSTEINS

The best are the cheapest. Why not have that kind? We have 200 large, well bred cows that are heavy producers. Some fresh and others due within 60 days. Tuberculin tested. Come and see them.
F. P. SAUNDERS & SON, Cortland, N. Y.



Purebred Registered
HOLSTEIN CATTLE

To promote general prosperity and their own business, bankers in many parts of the country are buying purebred Holsteins by the carload and selling them on time to the farmers of the community.

Every year it becomes clearer that with large yield cows the cost of milk and butter production can be brought down to a point that makes dairying profitable.

A herd of purebred Holsteins is an investment that combines safety with large dividends.

HORSES

YOUR BOY

Does he love horses? Then give him a chance. Set him up in business *at home on the farm.* Loan him the small capital required to buy a good yearling draft stallion and pair of fillies. In two years his fillies should yield two colts by his stallion, and the five should mature worth $3,000 or more. The gradual development of foundation stock, the increasing number and sale of surplus colts, and the steady income from service fees would soon establish for your boy an honorable and profitable business whose normal growth under good management should make of him a useful, prosperous and happy man. Write today for further details. ADIRONDACK FARMS, 57 Maple Street, Glens Falls, N. Y.

50 STALLIONS

and MARES, $250 to $1000 each
Write for my Illustrated Circular telling why I can save you money on the purchase of a Percheron or Belgian Stallion or Mare.

BLACK WALL MAP OF THE WORLD.

THE WORLD AND THE UNITED STATES AT A GLANCE.

A GREAT EDUCATION

AT YOUR FINGERS' TIPS.

This beautiful Wall Map, size 25x39 inches. On one side we have a complete, up-to-the-minute map of the United States in bright colors, showing the Capitols, Railroads, Rivers, large cities, etc. It also shows portraits of our 27 Presidents, and gives their biographies.

On the reverse side we have a map of the world, printed in a deep, ebony black. White and colored lines differentiate countries, rivers, lakes, cities and mountains. You never saw a map as black, as beautiful, as wonderfully enlightening as this map of the world. From this you may in a single day learn more than you could in a year's study of books.

Contrasting with the ebony black of the map are the flags and the coat-of-arms of all nations, in their flashy, exquisite colors. Our own seventeen flags are here in beautiful, bright colors—did you know that the United States had seventeen different flags?

And then, there's that wonderful Bible information. How many books, chapters, verses, words, letters does the Bible contain? How many books are classified as History, Poetry, Law, Prophecy, Epistles? Which books are exactly alike? How many times is the name of our Saviour mentioned? In how many languages is our Bible published?

Wouldn't you want to know these things? And wouldn't you want to know the many, many other things this marvelous Map of Knowledge possesses?

The Map will be sent, postpaid, for One New Yearly Subscription, or Twenty 10-Week Trial Subscriptions, or Two Yearly Renewal Subscriptions.

NEW YORK.

FATTENING WESTERN SHEEP.

BULLETIN 115 of the Missouri Station, gives the results of experiments in fattening 140 yearling sheep of uniform size and quality, raised on the range in Wyoming. The sheep were divided into seven lots of 20 each, and, excepting the last lot kept in the sheep barn in pens 6½x34 feet, each pen having a yard on the south side 6½x61 feet. Lot VII was fed in an open yard, with no shelter except the side of the barn, which gave protection from the west winds.

The rations used were: Lot I, shelled corn and Timothy hay; Lot II, shelled corn and clover hay; Lot III, six parts shelled corn, one linseed meal (by weight) and clover hay; Lot IV, six parts shelled corn, one cottonseed meal (by weight) clover hay; Lot V, shelled corn, corn silage and clover hay; Lot VI, shelled corn and clover hay, self feeder; Lot VII, shelled corn and clover hay without shelter. The feeding racks were 10-inch grain troughs with V-shaped hay rack, arranged so that the hay would feed down into the grain troughs. The rations were fed in two equal parts, half at 7.30 a. m. and remainder 4.30 p. m. All were started on one-fourth pound of grain each per day, gradually increased until in two weeks they got three-fourths pound and at the end of the third week were on full feed. Their appetites varied, and they were given as much grain as they would clean up. The hay which they left was saved and weighed back. The corn was good No. 2; the linseed and cottonseed meal the best that could be had and the hay choice native cut. The silage was free from mold. Salt was always before them and water in galvanized iron tubs.

A BUNCH OF FATTENING SHEEP.

The sheep cost $4.25 per 100 delivered at Columbia, Mo. Following are the weights at beginning and end of 98-day feeding period, and the price received per 100:

Lot I, average initial weight, 77.8, final 98.7; shrinkage in marketing 5.7 pounds; selling price per 100 $6.15; cost of feed $1.51; profit per head .514.

Lot II, average initial weight 78.15; final 101.25; shrinkage 5.75; selling price per 100 $6.35; cost of feed $1.73; profit per head .63.

Lot III, average initial weight 78.75; final 103.5; shrinkage six pounds; selling price per 100 $6.35; cost of feed $1.89; profit per head .572.

Lot IV, average initial weight 78.25; final 102; shrinkage 4.5; selling price per 100 $6.30; cost of feed $1.873; profit per head .561.

Lot V, average initial weight 78.35; final 105; shrinkage 6.5; selling price per 100 $6.35; cost of feed $1.644; profit per head .902.

Lot VI, average initial weight 77.95; final 102; shrinkage 5.2; selling price per 100 $6.40; cost of feed $1.688; profit per head .47.

Lot VII, average initial weight 78; final 97.6; shrinkage 4.6; selling price per 100 $6.30; feed cost $1.733; profit per head .335.

The average daily rations were: Lot I, grain, 1.17 pounds; hay 1.4; Lot II, grain 1.23; hay 1.72; Lot III, grain 1.23; hay 1.75; Lot IV, grain 1.23; hay 1.81; Lot V, grain 1.23; hay 1.33; silage .8. Lot VI, grain 1.55; hay 1.38. Lot VII, grain 1.23; hay 1.77.

As will be seen, the highest net profit was on Lot V, fed corn, clover hay and silage, .902.

A Brood of "Fireless" Chicks.

THIS is the story of an ordinary incubator hatch of chicks taken care of without artificially heated brooders. Besides a few weaklings and cripples which were killed upon removal from the incubator, 202 active chicks were taken from a 390-egg machine on April 30. A very ordinary hatch, but as good as the average where large numbers of eggs are artificially incubated. These 202 were placed in three small drygoods boxes and kept in the farm kitchen for a week; during this time most of those that were predestined to die young perished, and on May 8th, the 181 survivors were removed to a brooder three by six feet in size in the back yard. This brooder had two glass doors in front, a removable roof, and no heating apparatus; its interior had been painted with a kerosene and carbolic acid mixture, and a layer of chaff covered the floor.

The first weeks of May were wet and cold, so the chicks staid in the brooder and were covered at night with two thicknesses of bran sacking laid upon their backs and fastened at the edges by tacks pressed into the soft wood. On one specially cold day a lighted lantern was placed upon the floor of the brooder, and the cover was raised about an inch in front. This kept the brooder warm and the chicks were happy; it was the only artificial heat that they had had since leaving the kitchen. When a little more than two weeks of age the chicks began to assume the spindle-legged appearance of closely-housed youngsters and a small run was given them outside. The weather had become warmer and they needed but one cover at night. When this was tacked in place on three sides and the free edge lifted, the chicks ran beneath it as though called by a hen.

On May 24, when the chicks were a little more than three weeks old, the weather had become sultry, and it was decided to try them without any cover. There were a lot of them in a brooder originally designed for 50 chicks, and it was warm for bed covers. They had been reduced in numbers by the ordinary causes of chick mortality to 170, but had grown until they covered one half of the floor at night, even when packed together like figs in a box. This leaving so many chicks together at night without cover was an experiment, but the nights were warm and it was successful; they packed tightly but did not huddle, and were up in the morning before their owner. When he went out they were tapping on the windows for breakfast. Before this time their run had been removed and they had the liberty of the yard and garden through the day. They are now four weeks old; the weather is warm and they run all over the premises, returning to their coop at night or when a shower comes up. Cracked grains and dry mash are always at hand, they can help themselves to either loppered skimmilk or water at will; they season their food with dandelion or Alfalfa greens; form flying wedges to chase imaginary bugs; squeal loudly when the kittens chase them, and grow as fast as some of their high-toned cousins that have hen nurses and an ancestry with egg-laying records.

M. B. D.

Lessening Effect of Grass Feed.

1. What is paraffin oil and where can it be obtained? 2. Is there anything that can safely be given cows when on green grass that will lessen laxative properties, so that the manure will not be so disagreeable to handle?

S.

1. Paraffin oil is refined kerosene. Solid paraffin may be bought in cakes at the drugstore. 2. Feed each cow a pound of cottonseed meal or cake daily. This firms up the manure with certainty and at the same time is highly nutritious to the cow.

A. S. A.

Death of Calves.

For three years I have lost, by death, a number of my feeding calves. Can you tell the cause or suggest a remedy? The calves die at two or 2½ months of age; no appearance of bloat; will eat well and appear perfectly well at night or in morning when I feed them, and die in from 10 to 24 hours; do not usually seem to suffer much pain. I have sometimes noticed a slight discharge of mucus from the nose just before death. I have lost them on pasture and in the barn. I opened one and noticed nothing wrong except an enlarged gall bladder and dark spots on the liver. They are fed on freshly separated milk—froth removed—have a grain ration and grass or hay. The kind of grain fed has not been the same each year but has always included either bran or oil meal or both. I do not think they have ever suffered from constipation.

H. D. D.

Chautauqua Co., N. Y.

If you are sure that blackleg is not causing these deaths the most likely cause would be apoplexy from overfeeding and lack of exercise. It attacks calves that have rich feed and restricted exercise and is ushered in by a fit. Better reduce feed and regulate the bowels by dose of castor oil, or salts and make the calves take more exercise.

A. S. A.

DE LAVAL
CREAM
SEPARATORS
save much time and labor in summer

BESIDES GREATLY INcreasing the quantity and improving the quality of cream and butter De Laval Cream Separators save much valuable time and labor.

THIS GREAT SAVING OF time and labor counts for more in summer than at any other season and often alone saves the cost of a separator, aside from all its other advantages.

AS COMPARED WITH ANY kind of gravity setting the saving of man's time and labor and usually woman's drudgery with a De Laval is a big item in its favor.

AS COMPARED WITH other Separators the De Laval saves much time and labor by its greater capacity, easier running, easier handling, easier cleaning and freedom from need of adjustment or repair.

THESE ARE MERELY SOME of the advantages which make a De Laval Cream Separator the best of all summer farm investments, as every De Laval agent will be glad to explain and demonstrate to any one at all interested.

SEE THE NEAREST De Laval agent at ONCE or if you do not know him write us direct for any desired information.

A CLEAN DAIRY BARN
With Half the Work

By using a Porter Litter Carrier. It works on our Columbian Steel track, is easy running and will carry heavy loads. Our Perfect Cow Stanchions line up the cows without interfering with their comfort.

Porter Steel Stalls give perfect ventilation and light throughout the barn and make it easy to keep the cows clean.

We also make the celebrated Porter Hay Carriers and Barn Door Hangers. Send for catalog of our Perfect Barn Equipment.

J. E. PORTER CO., Ottawa, Ill.

You apply Sirenia Oil with a cloth

Sirenia Oil keeps flies from Cattle and Horses; fleas from Hogs and Dogs; lice from Poultry; ticks from Sheep. It heals sores and scratches. Sirenia Oil is the product of pure oils, will not blister, and is harmless for external use. You apply it with a cloth—you don't need to buy a sprayer to use it.

YOUR COW cannot fight flies and produce the milk she ought.

Ask your dealer for a dollar can. Just ask him for "Sirenia Oil," and do not buy a substitute. If he doesn't handle, send us his name and a one dollar bill and we will send a one dollar can, postpaid.

We will refund your money if not satisfied.

Send a dollar now; or write us a card for the endorsements of users who wouldn't be without it.

The Henyard.

THE EGG-LAYING CONTEST.

The extremely hot weather of the last week has been very uncomfortable for hens, and the egg record for the thirty-fourth week shows it. The egg production at the Storrs contest was 244 eggs less than the previous week. When the hen has to stand and hold her wings ont away from her body, and breathe with her beak open, as many have dnring the last week, her appetite for food diminishes, and she cannot produce eggs nnless she eats and digests a good supply of food. Anything that makes a hen uncomfortable is sure to lessen the output of eggs.

The highest score made this week is 58, made by Francis F. Lincoln's White Leghorns. Chas. N. St. John's pen are second with a score of 57; Merrythought Farm's White Wyandottes, Tom Barron's White Leghorns, Thos. W. Moore's White Leghorns, and Pen No. 39 from Storrs Agricultural Station, all tie for third place with scores of 56. P. G. Platt's pen of White Leghorns tie with Geo. A. Cosgrove's pen of same breed for fourth place with scores of 55 each. Barron's White Wyandottes still lead all other pens with a total of 1,418, the next best pen being the White Leghorns from Storrs Agricultural Station, Pen No. 42, which have a total of 1,378. GEO. A. COSGROVE.

Poor Hatches.

WHAT is the matter with my eggs? I have set my incubator with 140 eggs twice, test out first time 35, second time 40 eggs. I hatched out first time 20 chicks, second time 25 plus five cripples. On examination of eggs I found that each time 25 eggs with full-grown chicks were ready to hatch and remainder with chickens half grown. The eggs I tested at end of 10 days were found to be stale, and all eggs were put in when a week old. I feed my hens six quarts of mixed grain evening and morning, with a wet mash of beet pulp and gluten. All they want to eat at noon, and beef scrap in front of them all the time. I have 100 hens with a male bird for every 15 hens. E. S.

Canaan.

There are a number of ways in which these poor results in hatching may be accounted for. If there is nothing wrong with your incubator or its management, the trouble probably lies in lack of vigor in your breeding pen. Close confinement with heavy feeding and laying through the Winter so lessens the vitality of a flock as to make hatching of the eggs in the Spring difficult, even though the eggs are fertile and the embryos develop to a greater or less degree before dying. If you can turn your flock out upon range for a week or 10 days before incubating any more eggs, you should find a marked improvement in the hatchability of the eggs. You have double the number of males in the flock that should be needed. M. B. D.

Chicks Die in Shell.

WHY do little chicks die in the egg just before they are ready to hatch? I lost so many that way last year and again this year. Barred Rocks and Light Brahmas, also some turkeys. L. H.

The chief cause of death of fully developed chicks within the shell is probably lack of vitality, due to a corresponding lack of vigor in the parent birds. Artificial methods of incubation also fail to bring forth chicks that under natural methods would probably have been able to have broken the shell and emerged. This simply means that artificial methods have not yet been made equal in efficiency to natural. Failure of turkey eggs to hatch, where there has been no fault with the sitters, should also be laid to deficient vigor in the embryo due to some defect in the care or condition of the breeding stock. M. B. D.

Goslings Going Blind.

I HAVE 18 goslings, and they were doing fine until a couple of days and two of them are blind now. I have been feeding them a pint of cornmeal with a teaspoonful of salt. A. M. C.

I do not know the cause of the blindness. They should have a more varied food. For the first few days one of the best feeds is rolled oats, slightly moistened, with a little fine grit and not more than half the salt you give. Change gradually to a mixture of as many kinds of ground grains as you can get. I am using growing feed for chicks, with a little bran and cornmeal added, always with the grit, and I find it very satisfactory. Keep them on grass, of which they are very fond. W. H. H.

Defective Hatch of Ducks.

I GAVE a custom hatcher 160 duck eggs. When tested on the eighteenth day there were only 10 eggs not fertile, leaving a total of good eggs 150. When these began to hatch only 11 ducks came out of the shell, and the remainder were all full grown. When I was notified it was three days after first ducks hatched and on investigation found that the remaining ducks in shell were alive. In breaking the shell there was a queer substance which would run out, and the lining which is directly under the shell was so tough and hard that it required considerable strength to tear it open. I also noticed one black spot on the shell which looked to me as if it had stayed in one position so long that it became roasted or partly burnt. One other peculiarity was that in some of them their gizzard was like a growth just below their rectum. It looks to me like lack of care in turning the eggs, in giving proper moisture, and over-heating incubator. I ask your honest opinion, not that I intend to try to make the hatcher pay for eggs, as I have all ready paid for hatching, nor do I intend to hatch more eggs until I find just cause for trouble. J. L. S.

Vermont.

Assuming your statements to give the whole case I should conclude that there was something wrong in the management of the eggs, either in turning, cooling or sprinkling. There are so many factors in the successful management of an incubator that few become expert without some such experience as you describe. The black spots you mention could not be the result of scorching. The growth was not, I think, the gizzard, but a growth about the navel where the yolk of the egg is absorbed. W. H. H.

WHEN you write advertisers mention THE R. N.-Y. and you'll get a quick reply and a "square deal." See guarantee editorial page.

If not you can secure a good razor by doing some subscription work for us. The razor described below will be sent

For One New Yearly Subscription
or
Three Renewal Subscriptions

(One of these may be a renewal of your own subscription for one year.)

THIS fine razor is made of English Wardlow steel, ⅝-inch-width blade, hollow ground, hand forged and hand ground; double shoulder; ridged tang to prevent finger slipping; handle of hard, black rubber, steel riveted; nicely finished and strong; enclosed and delivered in strong, neat case. This razor was made up especially for *The Rural New-Yorker* by one of the best known and reliable manufacturers in the United States. We are authorized to guarantee that the razor will give satisfaction or will be replaced.

Your neighbor needs The Rural New-Yorker. If he is not a reader secure his subscription; if he is a subscriber secure his renewal.

THE RURAL NEW-YORKER
333 W. 30th St., New York City

PUBLISHER'S DESK

If the complaints we receive are any indication, James Wilcox, 921 Sixth Avenue, New York, N. Y., is still soliciting shipments of eggs from farmers. Our records regarding him go back some six or seven years. They indicate that he does not pay for shipments. Various excuses are made and we have some half dozen letters from him stating he is going out of business, but the complaints continue. We recommend cash in advance or no eggs.

I would like to ask you how to proceed to get my money. On December 13, 1913, I shipped a box of greens to New York to a commission merchant. He never got them until after Christmas so would not accept them and wrote and told me I would better take it up with the railroad company, as they were shipped by freight. To whom should I apply, and is it too late now to do anything? B. B. S.
New York.

We were able to get adjustment of this claim in about two months' time. This is not a bad record and we hope the transportation companies generally will put their records in such shape that when a clear case of loss comes up it can be settled promptly. As a contrast here is a record established by an express company:

A subscriber shipped a barrel of syrup to a New York State dealer. It was sent to his station by a teamster who neglected to take a receipt. The barrel was marked to go by freight but this was overlooked by the agent and the shipment went forward by express. The charges were, of course, excessive but inasmuch as no receipt could be produced the express and railroad company could not be held responsible and we could get no refund on the charges, which took away all the profit in the transaction.

Another subscriber shipped a quantity of poultry for which he received returns considerably lower than he anticipated. Investigation showed that he had neglected to take a receipt from the boat company, the poultry house had lost or mislaid their records and there was no way to ascertain the exact weight, and he was at a loss that made the transaction particularly unprofitable for him.

Both these instances go to show the protection a receipt carries with it. You cannot hope to adjust a claim with an express or railroad, or with a business house if you cannot verify your claims, and in filing claims the receipt is necessary.

I would like to ask your assistance in collecting a debt against the Newark Produce Company, Newark, N. J., of $331.20 for a car of Baldwin apples. Have received no money to date but lots of promises. R. E. G.
New York.

There was some delay about the delivery of this car of apples but check was sent for $281.48 after we had taken the matter up. It was reported that there was a shortage of at least six barrels of apples, and considerable other damage, but we were unable to get sufficient information or verification from the produce company to enable us to take it up with the railroad. There may have been mistakes on both sides in this controversy, but there is no explanation given for the refusal to send particulars that would enable the shipper to get redress from the transportation company. In the majority of cases we find the responsible houses ready and willing to give what information and help they can.

Will you advise me whether or not stock in the Ozark Mining & Milling Company, Ltd., Lewiston, Idaho, is of any value? Their agent persuaded me to take stock in it. In 1906 I took 100 shares and in 1907 100 more shares. I have received nothing yet. Several of my neighbors took 1,000 shares. What is best to do in regard to the matter?
West Virginia. C. E. F.

We are unable to find this concern. Mail addressed to them at above address is returned unclaimed. The company was probably organized for the purpose of selling stock and with no idea of conducting a mining business. The stock is of course without value.

I send you specimens of a new seedling cherry grown by myself and named by the U. S. Pomologist, "Perry." The authorities at Washington, Department of Agriculture, are very much pleased with this new variety; it is very firm, of excellent quality, a good shipper and a most remarkable keeper. It has been kept in a refrigerator in good condition five weeks. The tree is an upright grower, very healthy and a very prolific bearer; it is about 10 years old; last year was the first time we discovered any valuable traits about it. I am not quite sure as to its time of ripening; the specimens were picked today, June 24. I will pick no more for one week yet, in order to find its time of ripening, or maturing.
Landisburg, Pa. WILLIAM STEWART.

The specimen arrived in good condition and seems to justify the above description. It is firm, with acid flavor, and should make a good shipper and be especially valuable for canning.

I enclose some "literature" which arrived in the mail this morning. As you will see, my wife has been awarded a large prize in the shape of a conpon toward a piano, and the delightful thing about it is that she never heard of these people, or their pianos, or competed in any "chicken contest." I was about to send the stuff back with a sharp letter, when it occurred to me that it might interest you and perhaps help some of your readers to smell a rat if they were to win a similar "prize." H. S. R.
Massachusetts.

The above letter referred to the literature of the Associate Advertising Co. of 328 Federal St., Chicago. The printed letter advises the recipient that she has won a prize through answering some chicken puzzle. Another subscriber sends us a similar set of literature, and neither of them has replied to any chicken puzzle whatever. Notwithstanding this, a coupon was enclosed alleging to have a cash purchasing value of $108 at the warerooms of Lord & Co., Salem, Mass., or Lawrence, Mass. This prize puzzle scheme is an old fake that has been worked to the limit. No serious-minded person would expect that a coupon sent out in this way has any value, as the amount of cash they would be obliged to pay in addition to the coupon to get the piano will represent the value of the piano with a good big profit for the promoters of this scheme and the piano dealer besides. We flatter ourselves that none of THE R. N.-Y. readers will get caught on such transparent bait.

I am writing you this morning to tell you that it is now the 24th of June, and I have not yet received the 200 pounds of chick food that the Cloverdale Farms of Ransomville, N. Y., wrote you that they had shipped to me. I finally wrote to the freight agent at Ransomville asking them to look it up on their books and the enclosed letter with his answer written on it speaks for itself. You see they have never sent it. I wish there was some way that I could compel them to return the money. I think perhaps I should sue them for damages. I have a lot of late chicks which will be hard to sell and which I do not want to keep instead of 400 nice April pullets which I should have. A. A. P.
New York.

Our information is that the Cloverdale Farm Co., of Ransomville, N. Y., referred to in the above subscriber's letter, is under the management of one Mr. E. E. Cooley, formerly of Frenchtown, N. J. The stationery of the Cloverdale Farm Co. however, does not bear the name of Mr. Cooley or any other individual. When located at Frenchtown we were obliged for the protection of our subscribers to warn our readers against Mr. Cooley's methods, and it would seem that the change of location has produced no change for the better. It is said that leopards can change their spots, but it is our experience that they rarely do. To get redress through the courts as the subscriber suggests would be expensive and no doubt cost more in time and money than is involved in the whole transaction. While this subscriber has suffered a severe loss and disappointment, his experience may be the means of saving others from a similar loss.

I have always been a crank on farm papers and, of course, have taken quite a number. I now receive regularly a dozen or more, but you have them all beaten to a frazzle when it comes to exposing fraudulent advertisers, and I am only too glad to join your Anti-Fake Club. I long ago dropped Myrick's publications, J. A. Everitt's "Up-To-Date," Lewis's "Woman's Magazine," and a few others, and now I propose that we cull them closer than ever; no matter how well we like them in an agricultural way, if they won't look out for their readers' interests by carrying only reliable advertisers, let us refuse to be concerned about their papers. W. F. K.
Ohio.

That anti-fake club promises to be an important institution. It will, if consistently and persistently followed up, drive every fake advertiser out of not only farm papers, but out of every paper that seeks the farmer's trade. The people have the right view of the matter. The trouble has been that they have not known how to get at it. An occasional protest would not suffice. It requires concert of action in large numbers. This we now promise to have. Why should any farmer permit a paper to come into his house, with an alluring scheme to swindle himself or one of his family? J. J. D.

Limberneck.

WE are having much trouble with our Brown Leghorns. They are apparently perfectly well, have a red comb and do their duty in laying, until all at once they tumble and fall, stick their heads under themselves and are seemingly unable to stand up any more nor to lift their head. They lie around in this condition for a few days and then die. We are thus losing three and four, even five a day. We are feeding them corn and vegetables and besides they have free run in the woods and field, and abundant fresh water. L. H.
Texas.

These fowls have apparently been poisoned by the eating of unsuitable food of some kind, very likely having found access to some decaying carcass in the woods or fields where they roam. Search should be made for dead animals within their reach and those showing symptoms of poisoning should be promptly treated by giving them a dose of castor oil; about two teaspoonfuls; and confining them until recovery. M. B. D.

Leg Weakness in Chicks.

WHAT is the cause and cure of week-old chicks having something similar to rheumatism in their legs and feet? They seem perfectly healthy otherwise, but soon die after being stricken. P. C. S.

Leg weakness in chicks is an evidence of low vitality or possibly in some cases of actual rheumatism. It is frequently seen in young chicks kept in overheated brooders, particularly in those in which the floor is warmed, and all chicks kept upon board floors for more than two or three weeks are very apt to develop it. The remedy in most cases is to get the chicks out upon the ground where contact with the earth may overcome the evil effects of too close housing. Care should be taken not to overheat chicks kept in brooders and to hatch from stock kept under conditions conducive to vigor in the offspring. M. B. D.

Is Your Corn Safe?
Is it protected against vermin, fire and theft? Is it well-cured, ready for the highest market price? You can answer all these questions with yes after installing a
Marshall Corn Crib
Made of heavy galvanized iron that lasts a lifetime. Perforated body and ventilating shaft insure perfectly cured corn. Built along scientific lines, easy to erect, all sizes. Write today for free illustrated catalog, showing all styles.

It takes a Blizzard to fill silos like this
63-ft. Silos easily filled
These high silos are on the farm of Walter Flanders, automobile manufacturer, Orchard Lake, Mich., and are filled by a Blizzard Cutter.
Silos are getting higher every year. But no silo has been built which was too high for the Blizzard. It hustles silage to the top of the silo like a shot out of a gun. The
BLIZZARD
Ensilage Cutter
fills high silos without high power. Your regular farm engine will do the work.
The Blizzard has an enormous appetite. Makes you hustle to keep it going. Simple, easy to run, absolutely safe. Turns out nice, even-cut silage. Lasts for many years.
Send for new catalog giving all the facts.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending July 3, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914	1913
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.41 and $1.31 for B and C. Hotels and restaurants using two to three cans per day are paying 4½ to five cents per quart.

BUTTER.

Receipts are large and trading only moderate. Some falling off in quality has been noted during the week, so that buyers for critical trade have more difficulty than usual in getting suitable supplies. There is a fair call, both for local and out of-town trade, in qualities ranging from 22 to 24 cents.

Creamery, extra, lb	27	@	27½
Good to Choice	23	@	26
Lower Grades	20	@	22
State Dairy, best	25	@	26
Common to Good	18	@	23
Factory	16	@	20
Packing Stock	16	@	18

Elgin, Ill., butter market 26½ cents.
Philadelphia, western creamery, 27½ cents.

CHEESE.

Business is a little more active, and dealers less ready to move their choice stock at the top quoted price, except to regular customers.

Whole Milk, fresh, specials	14¼	@	14½
Average fancy	14	@	14¼
Under grades	10½	@	13¾
Daisies	15	@	15⅝
Skims, specials	11	@	11¾
Good to choice	10	@	11
Poor to fair	5	@	9½

EGGS.

The proportion of uniformly fine eggs continues small, even in receipts from sections reported to give more than ordinary care to candling and grading. In stock from nearby the same irregularity in quality is noted, the top figures representing but a small volume of business.

White, choice to fancy, large	27	@	28
Common to good	20	@	25
Mixed colors, best	25	@	26
Common to good	17	@	20
Western fresh, white	21	@	22

FRESH FRUITS.

New apples increasing in supply, selling mainly at 50 cents to $1 per bushel. The N. Y. State packing and grading law, in effect July 1 applies to all N. Y. State growers and dealers. Those unacquainted with it should get a copy from the Commissioner of Agriculture, Albany, N. Y. The boxed apple season, just ending, brought heavy loss to the holders. The fruit scalded badly in storage and kept so poorly when removed that retailers could handle it only at high prices. Large quantities of good varieties have wholesaled at New York below $1.50 per box. The evident lesson from this experience is that apple sales should be pushed to the limit during late Winter and early Spring, so that there will be no burden of holdings for June trade, when there is an abundance of fruit more attractive than old apples. Southern Le Conte pears are more plentiful selling at $4 to $6 per barrel. Some improvement in quality of peaches is noted, but few good enough to bring above $2.50 p crate. Strawberries from Western N. Y. are higher, a few bringing 20 cents, but most sales are between six and 14 cents. Muskmelons are a little higher. Prices for the last two weeks have been ruinous to growers.

*

Statistics show that immigration was 180,000 less than the previous year and 70,000 have left during the year, making a labor total of 250,000 fewer than a year ago.

*

Ninety-five New England cotton mills have declared semi-annual dividends amounting to $2,809,954, on capitalization of $121,120,100, or approximately at the yearly rate of 4.64 per cent.

*

The Geological Survey gives our production of petroleum during 1913 as 248,446,230 barrels, or about 24,000,000 more than the previous year. The price advanced 95.4 cents per barrel, making a gain in value of the whole yield of 44.4 per cent.

*

One fact that is likely to help hold the present advanced prices of wool is the shortage in the Argentine clip. Great quantities of Argentine sheep have been slaughtered for meat. Throughout Northern Montana many of the largest clips of wool have been sold at 20 cents. Prices of domestic fleeces in Boston have ranged from 25 to 28 cents.

*

The last week in June, 24,000 quarters of beef and 2,000 carcasses of mutton were shipped from Argentina to the United States. Total shipments since Jan. 1 were 433,000 quarters of beef, 90,000 carcasses of mutton and 50,000 of lamb. In 1913 London received 1,996,105 quarters of beef, 8,339,114 carcasses of mutton and lamb, from Australia, New Zealand and South America.

Care of Indian Runner Ducks.

THOSE who have raised other breeds of ducks, with good success, sometimes fail utterly with Indian Runners, and complain of their being delicate. If a few rules are followed there is no trouble in raising a large per cent of the hatches. Of course it begins with the breeding stock. Select vigorous mature birds and mate those not akin, five ducks to one drake, and not too large a flock, so every one has a good chance at the feed and water. Let water be clean and shells kept before them always. Cracked corn is good for a night feed, especially in cold weather, but the main feed should be mash, never sloppy, but just to the crumbly state, and consisting of equal parts wheat bran and corn meal, one-fourth the bulk Alfalfa meal, one-fifth beef scrap, and one per cent. oil meal.

Confine them in a house or small yard at night, and do not let them go before 10 a. m., when all eggs will be laid and can be gathered, washed and put in the cellar. Duck eggs spoil very quickly, and must be kept cool. If to be used for hatching, turn every day and do not keep them over a week if a good hatch is expected. Indian Runners are excellent layers. If fed for it they will begin at 4½ months old and lay steadily a good part of the year.

The eggs bring as much as, or more, than fancy white hens' eggs in the city market. Duck eggs require much moisture during incubation. If placed under a hen, dip in warm water every fourth day and the twenty-eighth day wet nest thoroughly. If in incubator, sprinkle with warm water every other day. Ducklings pip the shell and then lie idle 24 hours or longer before coming out. When taken from the incubator place in a warm brooder or in a covered box in a warm room and never let them chill. If hatched with a hen do not let her raise them, she will kill more than she saves.

The first feed, given four or five times a day is equal parts dry bread and oat flake moistened with warm water. After three days omit bread and substitute equal parts bran and cornmeal. After three days more give the same feed as to laying ducks, except that one per cent. grit is added. Warm water is given with each feed in very shallow dishes. Hot sun, wind and wet are fatal. They grow rapidly and get their second feathers at about 12 weeks. Weight is about three pounds at 10 weeks and all culls and surplus drakes can be marketed at that time. Let it be understood the Runners are not market birds. They are called the Leghorn of the duck family, and are well worth raising for egg production. However they make fine meat and are much preferred by many to the larger breeds. A swimming pond is not necessary for them, but a bath once in a while greatly improves their appearance and is much enjoyed. MRS. NILES GROVER.

A LITTLE girl, finishing her breakfast hash, looked up quaintly: "Mother," she asked, "what is hash when it's alive?"—Chicago Record Herald.

FARMERS' SECURITY BUREAU, NEW YORK
Agency Famous for Reliable Farm Help. No Branch. SIDNEY SULLIVAN, Expert, 99 Nassau Street

The FARMERS' BUREAU an agency exclusively for agricultural help. Only first class farm help and positions solicited. References investigated. Scientific advice on farm problems. Dept. R, 150 Nassau St., N. Y. Phone, 5565 Beekman

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

WANTED—Reliable married man to run 100-acre farm in Berkshire Mountains; state salary and experience. FARM, P. O. BOX 206, Madison Square, New York.

HUMOROUS

POP: "Yes, all engines have cow-catchers. Sure, sonny." Sonny: "That's funny. I thought they only needed 'em on milk trains."—Life.

"WAITER, this knife is blunt and the steak is like leather." "Ow'd it do to strop the knife on the steak, sir?"—Boston Transcript.

"Is there anything deleterious in these pies, ma'am?" "Certainly there is. I put in my pies all the best things going."—Baltimore American.

INDIGNANT POLITICIAN: "Why didn't you print all of my speech?" Country editor: "Well, to tell the truth, boss, we ran clean out of capital I's."—Puck.

"Is your husband troubled with insomnia, Mrs. Nurich?" "No, indeed. He doesn't sleep very well, but otherwise his health is perfect."—Buffalo Express.

"QUICK, quick my dear—everybody else is in the lifeboat. The ship is sinking!" "Wait a moment. I cannot be seen like this. The life-belt makes my coat pucker."—The Bystander.

HOTEL WAITER: "Come, sir, you really must go off to bed, sir." (Yawns.) "Why, the dawn's a-breaking, sir." Late Reveller: "Let it break—and put it down in the bill, waiter."—Punch.

"DON'T you know that you ought to scatter seeds of kindness?" Aw, what's the use? My neighbor's chickens would get them all if I did."—Boston Evening Transcript.

A LITTLE nine-year-old was laboriously looking up his spelling words in the dictionary when he came upon one whose meaning was perfectly apparent to him. He dashed off a sentence containing the word "capsize" and passed to the next. Imagine the teacher's amusement when he recited glibly, "My cap size is No. 6."—Delineator.

LAWYER: "Madame, I'm sorry to say that I don't see the ghost of a chance for you to break your uncle's will." Client: "Well, to be frank with you, I don't see the ghost of a chance to pay you for what you've already done if the will isn't broken." Lawyer: "H'm! On second thought, madame, I think the will can be broken."—Boston Transcript.

OBSERVING an unfamiliar shrub by a country roadside a student of botany stopped to make an examination. "Are you acquainted with this flower, young man?" he asked of a passing yokel. "Yep," the boy laconically answered. "To what family do you think it belongs?" Indicating a near-by house with a pudgy thumb the boy answered: "Higginses."—Puck.

MRS WHANN, the weeping widow of a well-known man, requested that the words "My sorrow is greater than I can bear" be placed upon the marble slab of her dear departed. A few months later the lady returned and asked how much it would cost to have the inscription effaced and another substituted. "No need of that, marm," replied the man, soothingly, "you see, I left jes' enough room to add 'alone.'"—Current Opinion.

THE teacher wanted some plums in order to give an object lesson during school hours, and, calling one of the small boys, she gave him sixpence, and dispatched him to the fruit shop at the corner. "Before you buy the plums, Willie," she cautioned, "you had better pinch one or two to make sure they are ripe." Little Willie flitted away. Soon he came back and smilingly put the bag on the teacher's desk. "Oh, thank you, Willie," said the teacher. "Did you pinch one or two as I told you to do?" "Did I?" was the response. "I pinched the whole bagful, and here's your sixpence."—London Opinion.

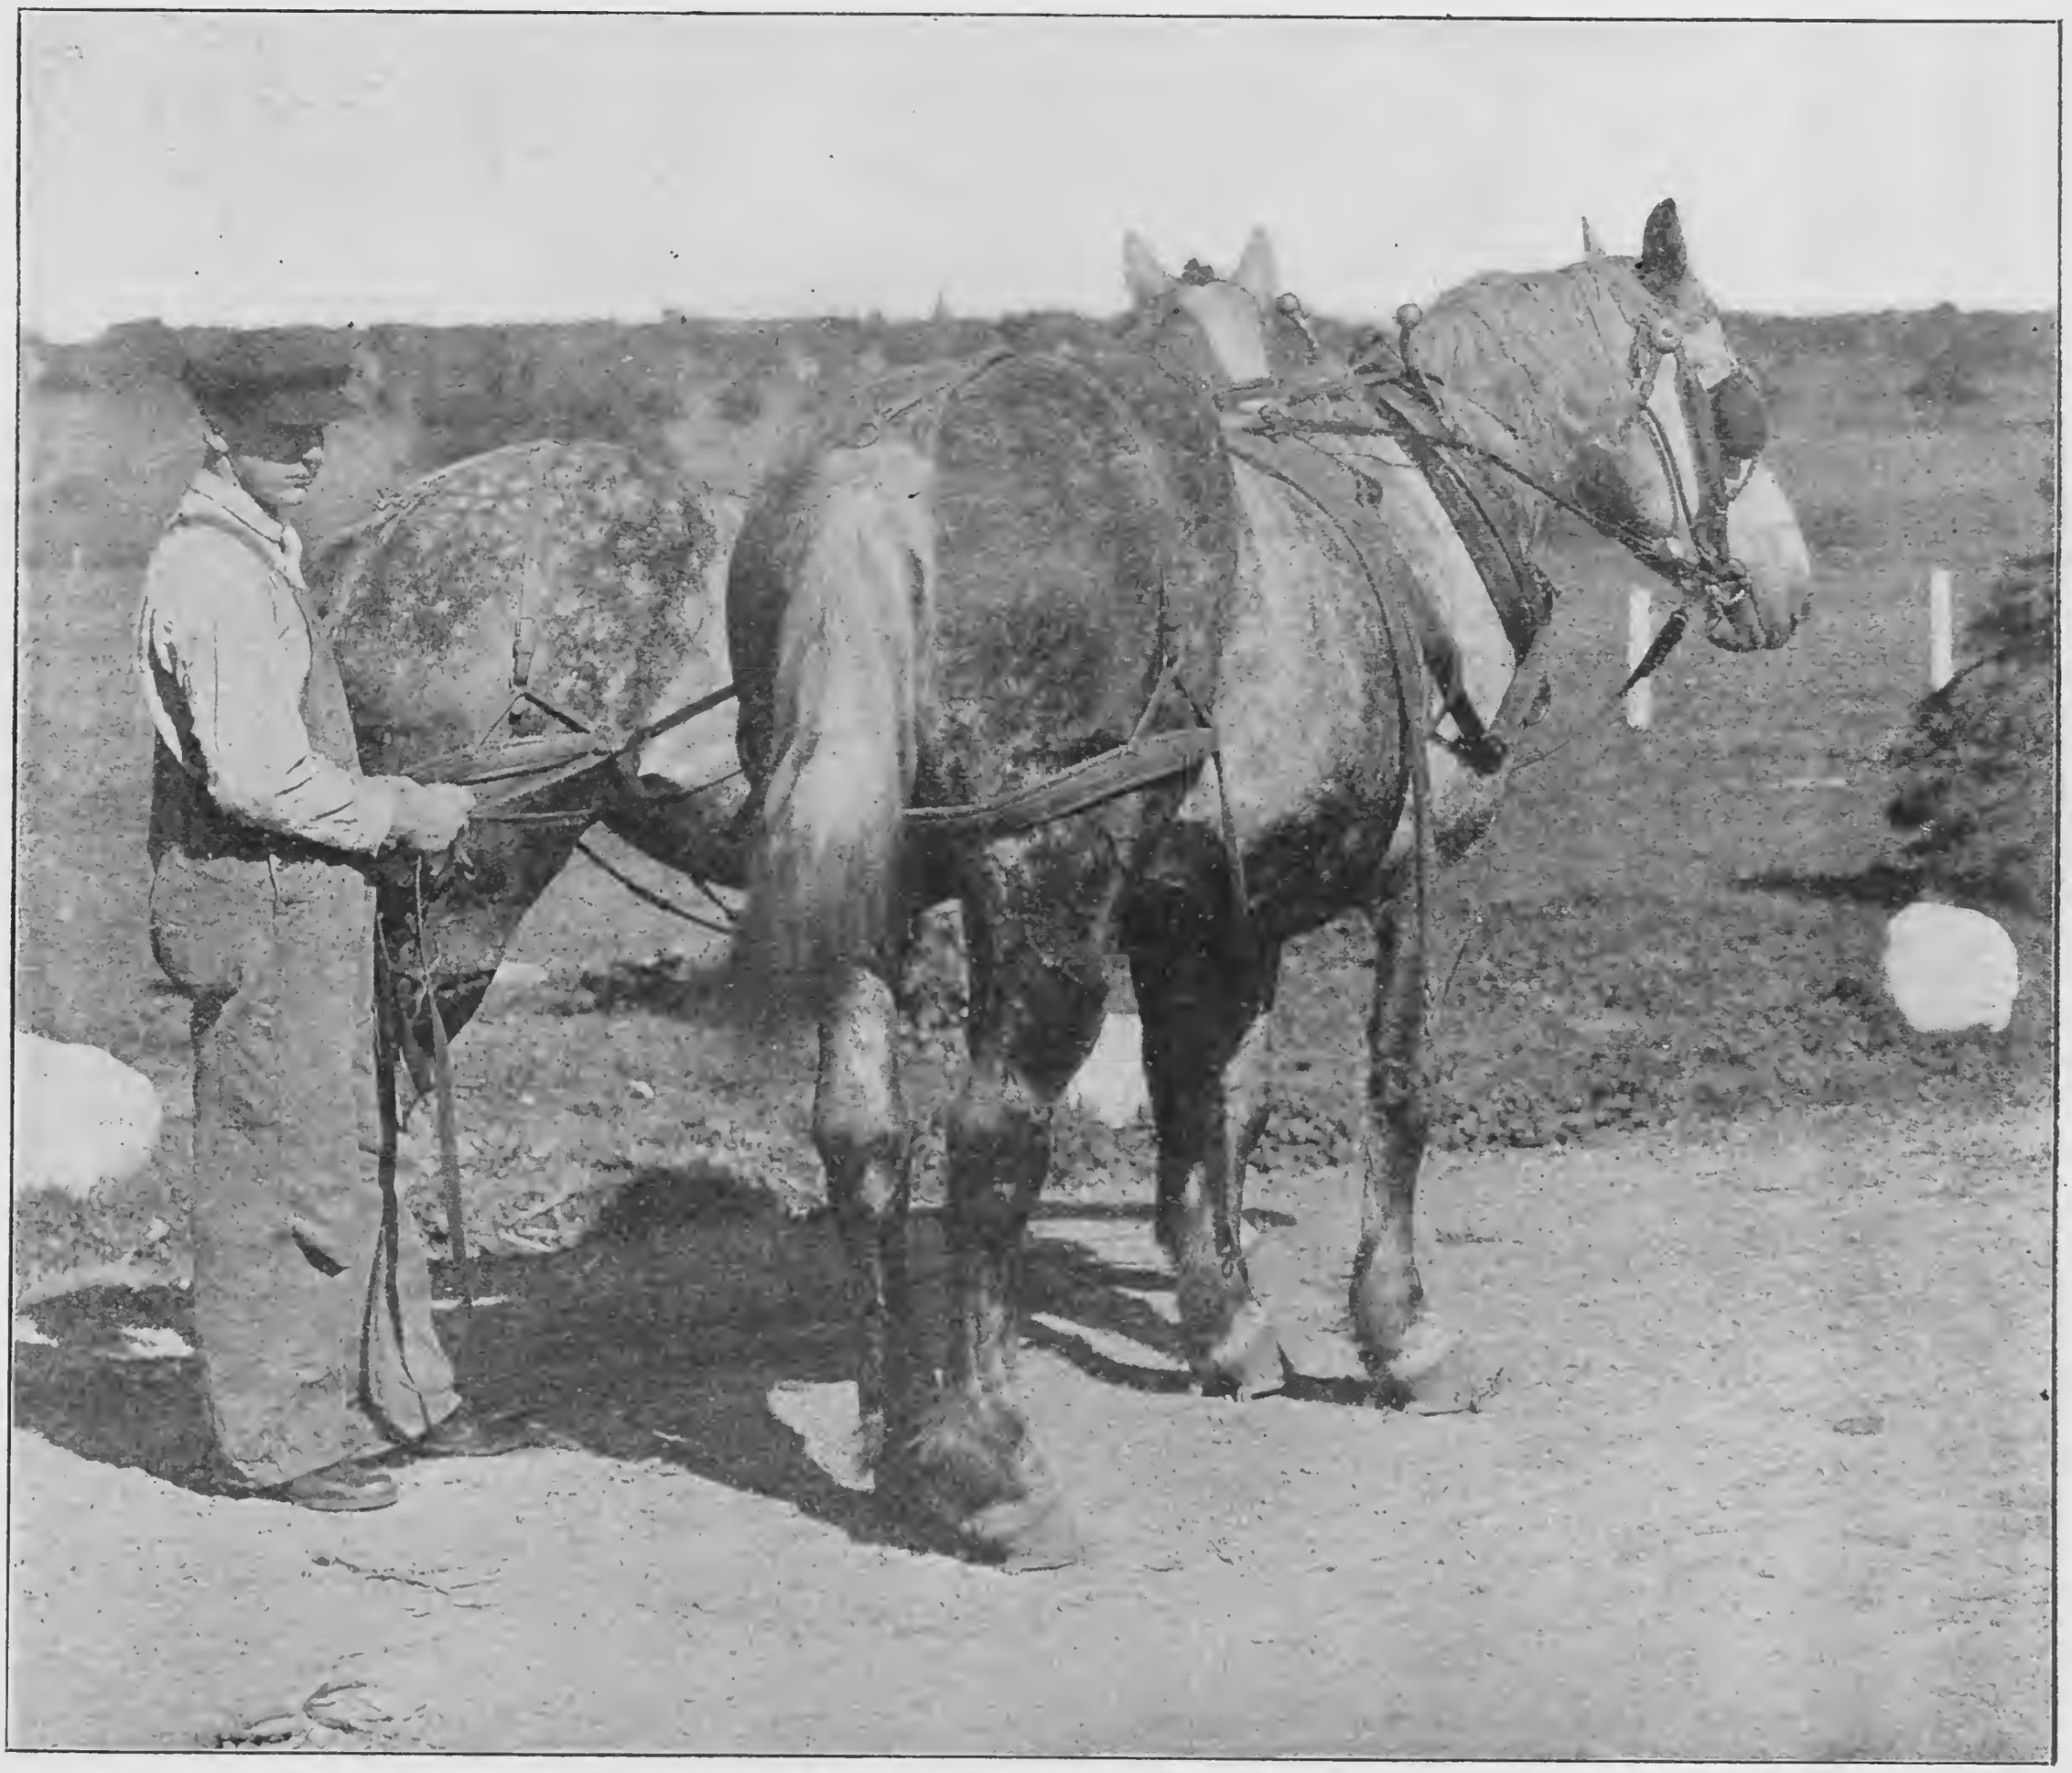
"DOUBLE CROPPING."

How Gardeners Keep Things Moving—Keeping Up a Succession.

I DO little of what may strictly be called companion cropping, or having different crops growing together, but I endeavor to have them following each other as closely as possible by starting other crops before the first planted ones are entirely out of the way. For instance, my earliest sweet corn was (June 24) ready for use. Between each row I have planted a row of Fordhook Lima beans as a succession to other rows planted elsewhere earlier. As soon as the corn is used the stalks will be pulled out of the ground, and the corn rows prepared and fertilized, and rows of green curled Scotch kale, Borecole, will be sown where the corn stood. These will be thinned out and the thinnings used as greens and the remaining plants given room to develop large heads that will be in their prime when the frost has killed the beans. As the corn rows were three and a half feet apart there will be plenty of room for the rows of beans and kale. I have usually four or five plantings of corn in succession. Between the rows of later corn, or the planting that will be in use early in August, I sow spinach broadcast and rake the seed in. This is sown about the last of July and is for Fall use. Then still later in September between either corn or some other crop I will put in spinach in rows to winter over for Spring use.

In early Spring, in late February, I usually make my first sowing of beets either Egyptian or Eclipse, and sow some radish seed with them of the early turnip-rooted varieties. These come up quickly and mark the rows where the beets are and are pulled out before the beets need the room. In planting the early beets a seed of chard is dropped every ten inches. The radishes come out first, and then the beets, and the chard holds the rows the rest of the season, the leaves being pulled like rhubarb for use. The vines of the early peas are turned under, and succession plantings of corn made on the land. Succession cabbages are set between the rows of the early string beans, and the bean tops are spaded under to help them as soon as the beans are used, and when these Succession cabbages are heading, onion sets are planted between the rows in Septem-



GOING TO THE FIELD. AN ILLINOIS BUSINESS FARMER AND HIS PARTNERS. Fig. 381.

ber, and the cabbages used and the onions cleaned and cultivated and the earth pulled to them as a Winter protection. The sets are grown from seed sown very thickly in late April, and they ripen in July. I use sets only for the production of early green onions in the Spring, and the sets are the Norfolk Queen, the earliest onion I have ever grown, as we usually here have them ready for use in late February. In September also I plant sets of the Yellow Potato onion to follow the Queen (which is not the Queen of the Northern Catalogues). The offsets of the potato onions are used as green onions and the main bulb ripens in June, and succession crops of string beans follow the onions.

Celery comes in after the early cabbages, and is grown after the Baltimore method in six foot beds, which are covered and stand where grown till used up. Between the latest corn, seeds of the Winter cabbage, the Late Flat Dutch, are planted in hills in July, and the plants thinned to one in the hill and the thinnings transplanted to any vacant space elsewhere. Plants that need the whole late season like salsify, parsnips, carrots and late beets are sown in June, for here I never sow parsnips and salsify early, as the roots get overgrown and poor. All these crops stand in the rows where they grew all Winter, and are given the full room after some earlier crop like the wrinkled peas which are over with us in June. Then in September any vacant place is utilized for Norfolk kale and spinach.

Between some of the later corn plantings the Fall turnips go in. In fact I endeavor to have something coming in at all times, Fall, Winter, Spring and Summer, and there is not a day in the year when we do not get some kinds of vegetables from the garden either outside or from the cold frames. Lettuce seed for the first Fall crop is scattered broadcast anywhere among other things that are worked out, as I want to get scattering plants and not plants crowded in rows for transplanting. This first lettuce sowing is made early in August and usually heads outside. Another sowing in September is set in the frames for Christmas. Some of these plants are set in open furrows to winter over for early heading in the Spring. These rows are between the rows of early cabbage plants from seed also sown in September, and if they winter well they head before the cabbages need the room. Then we sow lettuce seed outside in late February and transplant for a succession to those wintered over.

The frames in which the Christmas crop of lettuce is grown, are sown in beets and radishes in January in rows alternately six inches apart. I use the double glazed sashes, and these crops do very well. The radishes come out early and by the first of March, or a little later, the sashes are removed from the beets to cover the frames where the tomato plants from the greenhouse are set for hardening off. Then in late Spring or June, any vacant frames are filled with eggplants turned out of pots merely to keep the frames clean, two plants being set to each sash space. I keep my eggplants growing inside in pots till June and then have large ones to set out, and they generally go in between the rows of early lettuce that is cut out.

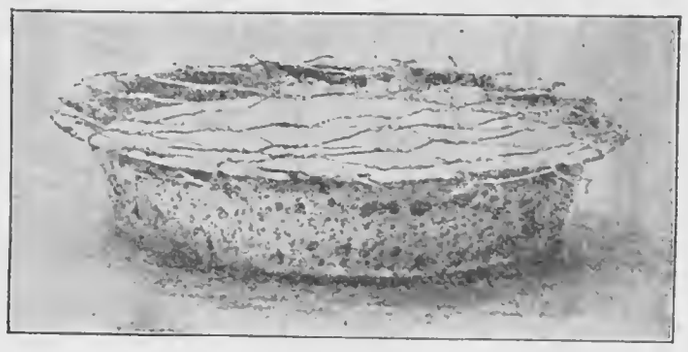
Maryland. W. F. MASSEY.

LATE CROP COMBINATIONS.

HERE we do nearly all cultivating with horses. No crops are planted in rows closer together than 2½ feet, and we cannot plant as close as gardeners operating on small areas and using wheel hoes. Neither do we intercrop to the extent practiced by such growers. Nevertheless we have found it profitable on different occasions to have two crops growing on the land at the same time.

We have often drilled in early peas in rows five feet apart and then started cantaloupes in hills between the rows of peas. The ground was marked for both at one operation. The peas were off before the cantaloupes required the entire space between the rows. We have also grown onions from sets in between rows of strawberries planted 4½ feet apart; the onions being marketed early in July, after which the strawberries had the entire space. There are a number of other combinations we could use for early planting but our experience is that the late crop combinations, of which there are a number, are best suited to our system of trucking. They pay well, and by using them the ground is kept busy the entire Summer; two and sometimes more crops are grown from the same piece of land and the soil is in good condition for early Spring planting.

Today (June 29) I have been plowing a three-year old strawberry bed. This will be harrowed tomorrow and in a few days will be planted in "Hoosier" white potatoes. These will mature here if planted as late as July 15. Last year we had over 1,400 five-eighth-bushel baskets on a five acre field, planted the first of July after berries. We get a crop of berries—then finish with a crop of white potatoes. The plot of ground which produced our early peas is now furrowed out in rows 7½ feet apart and will be planted soon in Boston Marrow squashes. If nothing happens they will mature before frost. Onions grown from sets are not yet out of the ground but we have Stone tomatoes set out



SOUR MILK VESSEL FOR CHICK FEEDING. Fig. 382.

four feet apart along the north side of every other row of onions. These were set out June 17, and are making a fine growth. The onions will be marketed in a few days, after which the tomatoes will be given a thorough cultivation and if all goes well will make a full crop before frost.

Another plot of ground from which a crop of wax beans has already been gathered will be planted in sugar corn for the Fall market. Early tomatoes on low ground can be followed by a crop of spinach, which will mature if planted before August 15. String beans, sugar corn, late tomatoes, late white potatoes, beets, spinach and a number of other crops can all be matured here if planted after July 1, and they can be arranged in so many different combinations that each grower can work out the one that suits him best. The beauty of them all lies in the fact that they can be grown with but little if any extra fertilization. Ground that has been well fed for early crops will have plant food going to waste during July, August and September, unless some crop is occupying the ground and making use of it. TRUCKER, JR.

New Jersey.

SCIENTIFIC PRODUCTION OF FINE APPLES.

From Plowing to Packing.

Part IV.

FACING THE BARREL.—Ordinarily the barrels will need some coopering before they are filled. Nails will need to be turned down, hoops tightened and bottoms removed. The smoothest and neatest head should be selected for the top ("head"), the head hoops driven down firmly and the bottom removed. A corrugated circular cardboard is first dropped into the empty barrel with corrugations next the wood. A lace ring or border of heavy white paper is sometimes placed on this disk, which adds to the appearance of the package when opened. "Facer" apples are then placed on this disk in concentric circles and with stems next the cardboard.

A PLANT OF BRUSSELS SPROUTS. Fig. 383.

Uniform fruit of good size and appearance should be used for this purpose, although it is not fair to use the choicest or largest specimens to be found. If the outer circle does not fit snugly, fruit of a different size should be used, but a mixture of sizes should not be used in order to make them fit. The second circle may consist of slightly larger fruit, but should also be uniform in size. Frequently three circles with a single center apple will complete the layer. If these different circles vary in size of fruit the increase should be toward the center, and where this is the case the "face" of the barrel will be a more exact representation of the quality throughout the package. Too many growers and apple packers have a faulty idea of proper facing, and it is not surprising that the name of the grower or those who are responsible for the packing fails to appear on the barrel.

FILLING THE BARREL.—After the barrel is properly faced the remainder of the filling is quickly done by basket, by allowing it to run in from the table, or otherwise. In the meantime the barrel is rocked so as to settle the fruit well into place. The crown layer should be made level, preferably with the stems upward, and the center slightly higher than the edges, which latter should stand about an inch above the stave ends. This will provide proper compression and insure a solid pack when the bottom is forced into place. Before placing the bottom, however, a corrugated disk—or better two—similar to the one used in the head is placed over the fruit. Either a screw or lever press is satisfactory for forcing the bottom into place. In case either is used the barrel should stand on a plank about 12 inches in width so as to permit of the arms of the press being promptly hooked over the chine. As soon as the press is in position the upper hoop is removed and the lower one loosened. As the press is operated the bottom pieces should be guided into place by the use of the flat side of the hammer, after which the hoops are driven down and fastened with 3d nails. Wooden strips or "liners" may then be nailed about the chine for additional security.

The head of the barrel should then be stenciled with at least the name of the grower, the variety, and the grade of fruit. These stencils may be secured of practically all firms dealing in fruit packages. Those made of sheet brass or copper are preferable. The barrel is now ready to be delivered to the dealer or storage, but if this is not possible at once it should be held in some cool place until delivery can be made. R. H. BELL.

MILKING TIME.

THE picture shown at Fig. 385 is said to be taken from life and certainly shows a new way of conducting a milking machine and raising hothouse lambs. We have had pictures of cows being milked by little pigs, goats and other animals and now and then there comes a man who claims that he saw a snake taking the milk from a cow. We have never seen that ourselves and doubt the possibilities of the story but it is a fact that some strange alliance are made with the good old cow, who is the mother among farm animals, ever ready to feed the hungry and take care of the thirsty.

SOUR MILK FOR POULTRY.

GREAT interest is being taken in the plan of feeding sour milk to chicks. We have had a number of articles about the beneficial effects of this, and the great success of our sour milk pen of Leghorns at the Storrs Egg Laying Contest has increased interest. This pen has been fed on sour milk from the first. It has made a remarkable record, and is now giving Tom Barron's White Wyandottes a great run for their money. We rather expect to see this sour milk pen beat out the English Wyandottes yet to the end of the contest. Many requests have come to us for information as to how this sour milk is fed. We therefore print the picture of a device used at the Connecticut Agricultural College. This is shown at Fig. 382, and the following remarks are printed concerning the feeding of this sour milk.

In the feeding of sour milk we have found it most desirable to keep milk before the chicks constantly, and in small shallow glazed or enameled pans. The chicks are prevented from getting into the pans by fastening a piece of coarse mesh wire screen over the pans. It is unnecessary to mix the milk with ordinary solid feed, like mash, in order to induce the chicks to eat it. If the milk has been soured in the right way, and if a new fresh supply is put before the chicks every day, or two or three times a day, it will be consumed as rapidly as is necessary. The broken bits of casein in the milk serve as objects of attraction; hence it is desirable from this standpoint alone, to fill the pans with the normal proportions of whey and coagulated casein. There are certain objections to mixing the milk with mash or other solid feed, one of the most significant being the fact that the milk-moistened food will tend to become mouldy, unless it is given in small amounts, and unless the pans or troughs are thoroughly and frequently cleaned. In all of our sour-milk feeding experiments there was not the least indication at any time that chicks suffered any injurious effects as the result of the milk diet. Since the milk was fed to chicks almost immediately after incubation, and many hundreds of them received this diet, the results clearly show that sour milk is not in the least unwholesome, but is an important agent in fostering growth and in reducing general mortality.

THREE BOYS AND $8,000.

Another Big Story of Apple Profits.

THE Boys World is supposed to be a publication for boys, and is published by the David C. Cook Publishing Company. At the head of its editorial page it prints the following very excellent statement:

"Before admitting any advertisement into the columns of this paper, we have been careful to investigate the responsibility and honesty of the advertiser."

A noble sentiment, and one which should be extended to the editorial parts of the paper as well as to the advertising. On the next page following this excellent resolution is an article on

"How Three Boys Are Earning $8,000 With An Apple Orchard."

This article is said to be by Sven T. Olson, of the U. S. Agricultural Department. As we have a family of boys at home who have not yet shown any such earning capacity, we were at once struck with the heading of this article, and we went on to read it. As nearly as we can make out, three boys in Michigan, who are now about 18 years old, have been for the last few years planting apple trees on several small parcels of land. It seems that these boys earned money at various kinds of work, and planted trees about 20 feet apart each way. The story goes on to tell how these boys took care of these trees until they have some 800 planted. The article is written in such a way that the author of it could get out through half a dozen holes in case he were obliged to stand up and face his statements. In order to make sure that this article was authorized in any way, we wrote to the Bureau of Plant Industry, at Washington, for information, and received the following letter:

Replying to yours of the 24th instant, with clipping from The Boys' World, headed "How Three Boys are Earning $8,000 with an Apple Orchard, by Sven T. Olson, of the United States Agricultural Department," I have to advise you that there is no record in this Department that Sven T. Olson was ever connected with the Department.

As to the accuracy of the statements in the article, we appear to have no information regarding the enterprise referred to. So many features of the article are contrary to general experience that the statements would need to be very fully authenticated to be accepted as true. The $8,000 return from the 800 trees that are said to compose the orchard is evidently a computation rather than an actuality, judging from the following statement in the article: "From what we already know of the orchard, and what authorities have written or told us, it should yield us in a very few years' time not less than $8,000 profit."

It would be interesting to know just what the facts are regarding it, and we are seeking information through several channels.

We are also conducting our own investigation, and if any one in Southwestern Michigan can give us any facts about this orchard, we would like to have it. If these boys are really making $8,000 they are most remarkable boys, and many of us who have good-sized families would be only too glad to know what these boys eat and live upon in order to acquire this wonderful power to make such wages. There are plenty of men who have grown fruit all their lives, who would be very glad indeed to make $8,000 a year. If there is any way of finding out the secret, we want to know what it is, and if this is a fake, we further want to know what the Boys' World means by printing such stuff as an inspiration for other boys.

A START WITH STRAWBERRIES.

WE want to set ont one or two acres of strawberries, but have never had any experience with them. We wish to put them in so that a good share of the work can be done with horses. We have no manure on hand now, but have a quantity of fertilizer; two grades, one lot of 10-8 and one of 10-4-6, that we can mix in any proportion. We are located in Otsego County, N. Y., about 1,700 feet above sea level and the soil is underlaid with hardpan. It heaves some in the Winter. We will have both oat and buckwheat straw this Fall that can be used for mulch. We would like to plow up old pasture that slopes to the southwest, if that would be suitable, and plant the kinds the best suited for our conditions. There is a good market here for the berries, for about all that are sold here are shipped in and are selling now for 15 cents per basket. The questions we wish to ask are: The location and preparation of the soil, the distance apart the plants should be set, the kind of fertilizer and quantity to use either with the plants or broadcast, the kinds of plants to get the best results, how often to cultivate and how deep to put on the mulch in the Fall.

New York. W. Z.

We would not think of plowing an old pasture and planting strawberries the first season. Such pastures are usually full of white grubs which would make quick work of the berry plants. Then again it would require too much hard work to keep such land clean. We should crop that land in corn first and if possible in potatoes before planting berries. The latter should go into the best and cleanest land you have. You cannot hope to plant strawberries now and have them yield a good crop next year. They should have been planted over two months ago for that. You can now set potted plants or layer plants from this year's runners and obtain a small crop next Spring, but it would not pay to buy enough potted plants to start your fields. It might pay you to buy 500 potted plants as soon as you can get them, put them out in rich soil and get as many

THE GRAIN HARVEST. FIG. 384.

runners as possible from them. You can transplant these runners where your crop is to be grown finally or you can plant them close together in some convenient place where they can be mulched and set out next Spring. Our advice is not to think of putting the old pasture land into strawberries. While we have set out plants in New Jersey all the way from April 1 to Thanksgiving and had them live, early Spring is the best time. As for varieties—that matter varies so with climate and conditions that we would rather hear from local growers in Otsego Co. On strong land not much nitrogen is needed for berries—potash and phosphoric acid with a small amount of dried blood will answer. We should apply the fertilizer on a wide strip along the row when the plants are set out. By planting three feet apart each way you can work with a horse both ways until the runners are active. Then let them run in rows one way so as to cultivate the other way and leave hills or a matted row as best suits the variety.

"FIVE MINUTES FOR REFRESHMENTS." FIG. 385.

AN expert pruner tells of this side of his work: "I am making about 70 cents per tree, and prune about eight trees per hour, so I don't have much rest for my right arm. All the cutting is done with hand shears (I have used the saw three times in two weeks), so you can judge the condition of the trees." Let's all go to "Summer pruning. This is only one side of it, for not one man in 1,000 could earn such wages.

SOME GARDEN CROPS

That Are Profitable in a Small Way.

OUR big brothers, the bonanza gardeners, who raise celery, and lettuce, and onions, in 10 and 20-acre fields, and ship their products in car lots only, probably have little love and appreciation for such things as Brussels sprouts, kohl-rabi, bunching onions, and some others as crops worthy of their consideration and efforts. Brussels sprouts, if successfully grown, are profitable in a small way, but the demand is limited and we cannot grow them by the acre with any hope of securing the 20 or 25 cents per quart of the tiny cabbage heads for the 5,000 or more quarts which a good gardener might grow with ease on the one acre. But the small market gardener who has a local trade, selling his vegetables directly to private consumers or to local stores, or who keeps a stand in the city market, will find good returns in the production of the limited quantity he can find or make sales for. A large proportion of Americans are wholly unacquaint with Brussels sprouts; many do not even know the name of this vegetable. But if it were more freely offered, more people would learn to like the little heads of refined cabbage flavor, and be willing to buy (or grow) it. I had many plants last Fall that gave a plump two quarts of sprouts per plant. When private consumers pay a quarter per quart, one cannot get a half a dollar much more easily than by picking off one of a plant that only requires two feet one way by three the other.

I have had my best success in growing Brussels sprouts when I sowed seed in Spring, and set the plants rather early for late cabbage plants, say middle of June or before. The seed I sowed came from Long Island. The pictures of the Brussels sprout plant as often found in seedsmen's catalogues probably represent the seedsman's ideal, or what he thinks the plant should look like. The camera, however, shows the thing as it is, not as we would like to have it. It is an interesting and attractive plant, even if it does not come up to the seedsman's ideal in regularity and productiveness.

Kohl-rabi is another of these vegetables, little in demand and not appreciated as it really deserves, but easily grown and profitable for the grower who finds customers knowing how good it is. It should be used while young and tender and succulent, and will then be sure to please the palate of people who like turnip, and especially-refined turnip flavor. Our garden books usually teach growing it like cabbages, namely starting plants in seed bed or under glass and transplanting to stand six inches or so apart in the rows. An easier and better way is to sow the seed thinly directly where the plants are to make the crop, and thinning to a few inches apart. We usually do this thinning when the first plants have already made some bulb (a ball-like thickening of the stem just a few inches above the surface of the ground). We gather the largest of these bulbs for use or for bunching, leaving the smaller ones to come on later. Seed may be sown very early in Spring (the plant being as hardy as a cabbage) and at intervals of a few weeks for succession.

T. GREINER.

NOT WOMAN'S WORK.

THE picture shown at Fig. 384 is like many others which attempt to represent the farmer's daughter or wife out in the harvest field doing a man's work at raking or shocking grain. Some people go on to preach a sermon on industry from these pictures. We are told how the farm woman can be of great service to her husband and brother by doing a man's work in this way.

The fact is that these pictures rarely if ever amount to more than a fancied presentment of some girl usually fresh from the city who wants to be pictured in some unusual way. It is a mistake for the average woman or girl to attempt to do hard farm labor. Some of them have been obliged to work in this way in order to help save the farm, but this kind of labor is not woman's work and the average woman will receive more damage than help from trying to do it. An occasional hour spent in the harvest field at such work is well enough but the modern American woman should not be expected to do a hired man's labor and those who expect her to do so will sooner or later regret it. Woman's work as a home builder is her greatest possible service to her family.

FARMERS' CLUB

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Raking Up Stones.

WILL you suggest a tool for clearing stones from about six acres? Stones are the size of a large hand, some bigger. C. K.
Rockaway, N. J.

We do not know of any special tool for the purpose. Several of our readers have reported use of a steel rail from a railroad track. With a team at each end this was dragged across the field and pushes the stones into windrows. We have known farmers to plow out deep ditches and then rake or throw the stones into them. One reader reports the successful use of oyster tongs such as fishermen use. Other use a heavy log with pins of wood or iron driven into it projecting forward so as to gather up the stones and push them on. A plank with such pins is hardly heavy enough. A tool made like a hay rake with heavier teeth would answer for small stones but probably a heavy scraper with spikes attached would be best.

The Peach Borer Once More.

I HAVE a peach tree in my yard on which I noticed a mass having the consistency of honey at the base of the tree and upon removing this mass I found that the bark was entirely gone. I removed all that I could and found a white worm under the bark at one spot and a red worm at another. I then painted the injured parts with ordinary paint containing lead. Will you tell me whether either of these worms was the damage maker and which one? What could I do to prevent the tree from being further attacked by these borers?
New York. M. L.

This is the peach borer which we have often described. The egg is laid at the base of the trunk by a moth in late June or July. The worm or borer hatches and works down toward the root under the bark. You will find the mass of gum which you noticed filled with sawdust or little chips which the borer has guawed out of the tree. The only way to make sure of this pest is to dig it out in the Fall and again in Spring. Scrape away the gum and find the passage which the borer has made with a sharp knife, cut *down* through the hole until you find the iusect at the bottom. Do not cut across the trunk but slit the bark *down*. Paints and smears will not prevent all the damage. They may prevent the moth from laying her eggs low down but there will be some borers at work in spite of these protectors. The best one we know of is a thick lime-sulphur mixture sprayed or wiped on the trunk. Lead paint often kills the tree. Digging out is the only sure remedy we know of.

Success With Rye and Vetch.

REFERRING to the article on "Fraud in Vetch Seed," page 888, having used rye and vetch as a cover crop for three years on poor sandy soil, and having at last succeeded in getting a splendid stand of the vetch, I am convinced that the lack of soil inoculation is responsible for the failure of the vetch to catch in more instances than poor seed. I started with imported seed aud sowed it on eight acres of the best land I had, but the soil was in such condition that I could not get a catch of clover or Timothy after three trials. We had lots of snow the following Winter and the vetch came through in good shape, but the plants were scattered and spiudling. However, it was vetch or nothing, so I again sowed it and it survived a cold Winter with but little snow, much to my surprise, and the crop was double that of the previous year. I cut the rye and vetch for hay, but did not get into the field early enough so that a lot of the seed shattered out. My third planting was last September, and being rushed with work, I broadcast the seed and disked it iu, leaving the ground rough on the theory that it would hold the snow better. This Spring I cut nearly eight tons of rye and vetch hay from six acres of the eight-acre field, leaviug the other two acres for seed. The vetch is more than half of the crop. I have had similar experience with other fields, that is a gradual increase in the vetch as the soil becomes inoculated. Had I turned the ripened vetch under the first season, no doubt the advance would have been more rapid, but I needed the feed. Our soil is like that of easteru New Jersey and Delaware—very sandy, and I would not be able to get along without vetch and rye, as a cover crop, to help out the corn fodder, and, when I can afford it, to turn uuder to add nitrogen and humus to a soil very much iu need of both. F. B.
Ottawa Co., Mich.

R. N.-Y.—No doubt inoculation pays but we believe that great quantities of Spring vetch are worked off for the more desirable Wiuter variety.

Sowing Buckwheat.

I HAVE a field of rye which I cut and fed to cows. I was thinking of plowing and sowing buckwheat to plow under this Fall. Would you advise me to do that or what would you advise? This field is very dry and sandy loam. Raised corn last year and used four cords manure per acre with some fertilizer. Will buckwheat grow on such dry land? What kind of buckwheat is best? How much per acre? How would it be to sow buckwheat in corn last cultivation, where witch grass is bad on same kind of soil as mentioned before? N. F. K.
Massachusetts.

It depends partly on what you will do with the land after the crop is plowed under. We would not plow in the Fall and leave the ground bare, but would keep something growing through the Fall and Winter, and plow under in the Spring. For this purpose our suggestion would be to sow two bushels of Japanese buckwheat, three pecks of rye, and two pounds Cow-horn turnip, all well worked into the soil. Then let the field alone until next Spring. The buckwheat and the turnips will be killed out during the Winter, but the rye will come on and give a good yield, to be plowed under next year. There may be some local reason for plowing this Fall, but if not we should not plow until next year when the new crop is to be put in.

Ownership of Property.

I OWN half of an undivided shore about half a mile long, and on that shore I have built a fish trap. I built this trap about six years ago, and got a license from the city to build into tidewaters. The man who owns the other half lives in California and is going to sell to a man living here. Can this man claim half of my fish trap, or can he charge me rent for the shore? Fish trap cost about $300 to build. J. A. D.
Maine.

You do not state whether you had the consent of the present owner to build the trap, and that it should remain your property. Then considerable would depend on how you affixed the trap to the land. If it is fixed securely to the soil so that it cannot be taken away without injuring the property, it becomes part of the realty, and the new owner would be entitled to his share, unless you had some arrangement to the contrary, and he could charge you rent for the use of the shore. Your best plan is ot write to the present owner and see if you can get a statement from him that you are the owner of the trap and ask to put a statement to this effect in his deed to the new owner and then get some writing from the new owner that he recognizes your owuership of the trap. M. D.

MAIL BAG.

Killing Dock.

I HAVE a piece of clover land quite full of dock. It lies in the low land so it is very wet and cannot be plowed in the Spring. Can you tell me any way to get rid of it? I am afraid it will spread. If the clover is cut before the dock seeds ripen do you think there is danger? E. H.
Massachusetts.

We do not know of any way of cleaning out dock except the laborious old fashioned plan of digging it. We have spent a good many days at this job. The tool for the purpose is a sharp spade, or what is known as a spud, which is really a narrow spade with a sharp edge at the end of a long stick. The spade or the spud is pushed down into the ground beside the dock so as to cut off the root five or six inches underground. Then the top of the dock is pulled out and turned up to the sun to be pastured. A small handful of salt dropped into the hole after the dock is cut off will help.

Hydrated Lime.

I BOUGHT hydrated lime at 75 cents per 100 pound bag from a large local dealer, but have been told that it is not good, that I should buy the quicklime, bury a lump in dry ground and in few days it would be perfectly slaked. Is that correct? A. W. P.

We prefer the hydrated lime to other kinds except that it costs too much. This form of lime is the lump or "quick" lime ground fine and then sprayed with just enough water to slake it perfectly. This makes it very fine and even and more comfortable to handle than other forms. A pound of lime in this form costs too much for ordinary use. Lump lime need not be buried in the ground in order to "slake" it. Left anywhere in moist air it will absorb moisture (which is slaking) and crumble to a powder when it is ready for use.

Experience With New York Help.

AFTER reading Mrs. F. W. Cole's article in your last number, we feel impelled to give our experience with the help received from the places named by Mrs. Cole. Last Spring we received a man from the Jewish association which proved to be a very intelligent German who wanted to get acquainted with farm work, but was entirely ignorant of auy kind of farm work. He had been a traveling salesman, but will say this, he did the best he could according to his knowledge of the work. About middle of July he went to New York to engage in a swimming contest which he was preparing himself for about all the time he was here and that was the last of him. The next one came from a farm school and a bigger fraud no man ever had. He staid about a month and then wanted to go, which we gladly assented to. At noon when my son went to his room his gold watch was gone; that is the last we have seen of mau or watch. We sent $5 to an agent this Spring to have him send us a man as he advertised that he had men for farm work. In a short time we received a letter from him saying that he had sent a man but the man never showed up, nor the $5 either. We do not consider we have got 33% on one dollar in work out of the money spent on N. Y. help. We have about made up our minds that we can't do business with the misfits of the city. It is about like all the rest of the farm business. We give out best of the men we raise and take the poorest of the city.
JOHN ANDERSON & SON.

WANT TO KNOW.

Growing Ever-bearing Raspberries.

CAN any reader report as to experiences with Ever-Bearing raspberries? There are reasons why, for me, they will be very useful if they produce enough fruit at last bearing to make it worth while. They have not, so far, but that may be my fault. For the ordinary red raspberries it is recommended to cut back the tops of the plants but it that is done on the ever bearing, will it not kill the new fruit buds? They seem on the tips. The bushes are slender and the weight of the berries brings them to the ground and there they lie iu the mud. I should like directions for getting results. I have in mind to run wires down each side of the row, supporting the wires by strong posts and thus hold the plants off the ground, but I am not convinced that the ever-bearing are worth the trouble as yet. M. P. L.
Maryland.

KEEPING DAMP OUT OF STONE WALL.—I saw an inquiry about field stones for building. I am just building one bungalow now, 30x36 feet, with all field stones and concrete. I would like to find out what to do to keep out the damp. Somebody has told me to put a good coat of asphalt on the walls. I don't know whether it is right or not.
New Jersey. C. P.

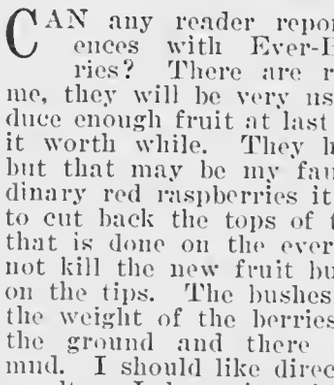
Plant LOVETT'S Pot-Grown Strawberries
this Summer and have an abundance of big, red, luscious berries next June
I am a pioneer in growing Pot-Grown Strawberries. I have been growing them for 36 years. I offer properly grown plants of all the choice new and good old varieties—but by far the finest of all strawberries are the Van Fleet Hybrids, the



Early Jersey Giant, Edmund Wilson & Late Jersey Giant
now being introdueed by me. They yield enormously, have the delicious flavor of the wild strawberry, and are as large as small apples. These three varieties give a long season of fruit, from the earliest until the very latest. Write for my booklet, mailed free. It tells all about the Van Fleet Hybrids, illustrates and describes a score or more of other fine varieties (including the best of the Everbearing Strawberries), and gives *full cultural instructions*.

COVER CROP NOTES.

Cover Crops in Peach Orchard.

I HAVE half an acre of oats and peas in a peach orchard that I shall cure for hay about the middle of July. What can I put in the ground after the oats and peas are off that will give me a crop of hay for next Summer? I generally sow rye, but thought you might suggest something else that I could put with the rye. You may think I am asking too much of the peach orchard, but Prof. Surface tells me the ground is too rich for the good of the trees. I also have half an acre of Evergreen sweet corn that I would like to seed with something that will give me early fodder, or cure it for hay and get off in time for corn again.
Factoryville, Pa. L. L.

In such a case we should work up the ground after harvesting the oats and peas with a cutaway or plow, fit the soil and sow fodder corn thickly in drills three feet apart. Give fair cultivation and if the season is at all favorable, you ought to have a heavy crop of corn fodder. This corn fodder makes a small thick stalk, which is usually very satisfactory as a substitute for hay. We have found it excellent for feeding all kinds of stock through the Winter. You can if you like sow rye at the last cultivation of this corn for a Fall and Winter cover crop. In the sweet corn we should sow equal parts of rye and barley. After the corn is taken out the barley will make a heavy growth, and may be cut in October for green fodder or hay. The rye will live through the Winter and give a Spring crop for fodder or for turning under.

Cover Crop for Orchard.

WHAT treatment do you recommend for a 25-year-old orchard that was neglected for the first 20 years, but is now in fine thrifty condition and bearing well? Past few years has been fertilized with nitrate of potash and slag with cover crops of rye turned in, and then cultivated between the rows. Many of these trees are growing too fast, and I would like to check growth about August first with cover crop that can hold over next Summer or be cut early for mulch. S.
Bolton, Mass.

In a case of this kind you need a crop or combination of crops which will make a quick rank growth during the Summer and Fall, when such land is active and most likely to be filled with nitrate. From our experience you should use for this purpose two bushels of buckwheat, three pecks of rye, two pounds of Dwarf Essex rape per acre. If this seed is well put in there will be a heavy growth during the late Summer and Fall. Buckwheat will be killed out by frost and the rape will die during the Winter. This will cover the ground like a mat, but the rye will come on and give a heavy growth for next year, which can be cut and piled around the trees. Or in place of the rape, if you desire a permanent mulch, you can use mixture of Timothy, Red-top, Blue grass and White clover.

Cover Crop for Blackberries.

I HAVE several acres of blackberries in full bearing, set in rows six feet apart and kept clear of grass and weeds between the rows. Would it be advisable to sow something between the rows before or after picking (which comes in the month of August with us) for a Winter cover crop for the ground that could be scraped up against the bushes in rows in the Spring for a mulch, with a snow-plow shaped scraper, and if so which would be best? I have read about vetch, rape, Cowhorn turnips, etc., as a cover crop and fertilizer, but have had no experience with them. I want something that will winter-kill, and am afraid vetch would grow in the berry rows in the Spring and have the effect of weeds or grass the following season.
Cortland, N. Y. A. S.

We have a number of calls from parties who desire a cover crop that will not live through the Winter. The object of this is to avoid plowing in the Spring. Rye is the foundation of most northern cover crops, but this is practically sure to live through the Winter and thus would not answer. In most cases vetch, after it becomes acclimated will live through the Winter and make a heavy growth in Spring. For a crop which is to be killed out through the Winter probably a combination of barley and Dwarf Essex rape will be as satisfactory as anything. The barley and rape will make a good growth during the Fall, covering the ground thickly. A few plants of the rape may be found in the Spring, but the great bulk of the crop will be killed. For this purpose we think the rape will be better than the Cow-horn turnips. The barley and the rape may be seeded after the middle of August by working the ground with a cultivator, and will add a good quantity of organic matter to the soil.

Bonding New Concrete to Old.

CLEAN off with clear water and stiff broom the surface of the old concrete. Mix one part commercial muriatic acid or hydrochloric acid and three parts water (or use bonsit or ransomite, mixed according to directions with hot water) make several applications one after another with a brush containing little or no metal. This will not injure the concrete, as the acid does not sink to a sufficient depth before it is neutralized. This will have the effect of removing the cement from the top surface of each grain of sand or piece of stone and the other aggregates that may have been used, exposing the clean surface of these aggregates in exactly the same condition as they were before being mixed. After applying the acid, wash the surface with clear water, scrubbing with stiff broom or brush removing all the dead particles. While the surface is still wet (and it should be thoroughly wet) apply the new concrete. Protect this new concrete by keeping it damp for at least a week. Do not let it dry out at any time during the first week. It will be found that the new concrete will bond to the old as strongly as if both had been mixed at the same time. C. B. L.

Roughing a Concrete Floor.

IN reply to inquiry regarding slippery concrete, on page 832, I would say that I have asked the same question many times. We never received an answer, and finally tried an idea of our own, and the experiment has proved satisfactory in every way. Apply to the floor a heavy coat of tar. The floor should be dry and clean, and the tar slightly warmed. Apply with an old broom. If a new broom is used, cut the splints off about half way to make a stiff brush. After the tar is applied, cover with very coarse, sharp sand—about one-half inch thick. Leave the sand on and use the floor, until the tar takes up all the sand it will. Then the floor may be swept. This can be repeated every year if necessary, as it is inexpensive and easy to apply. It takes the same color as cement, and is hardly noticeable, and does away entirely with the slipping. CLAUDE M. BULSON.
Otsego Co., N. Y.

Cold Storage Eggs.

IS there a limit provided by law for the length of time eggs shall remain in cold storage? M. S.
Florida.

On application to the Bureau of Chemistry at Washington we have the following:

No laws have been enacted regulating the length of time in which eggs may be held in cold storage. The sale of eggs which have been held in cold storage until they are unfit for food would, of course, be considered a violation of the Food and Drugs Act. It would also be considered a violation of the Act to sell storage eggs as fresh eggs.

Planer Shavings in Manure.

I LIVE in a suburban place where several acres are available for truck. The land is quite heavy, but can be kept in good condition if regularly worked. On this place there are kept 10 or 12 horses from which there would naturally be quite enough manure available for this piece of land, but the horses are bedded with planer shavings, principally of pine with some oak. I know from experience that the tendency of pine shavings is to sour the land, and I would like some advice as to how this manure could be treated in compost to overcome this defect. E. B. W.
Wilmington, Del.

We have frequently discussed this question of planer shavings. These shavings contain an acid and when used in large quantities will sour the land. There are two ways of overcoming this trouble. One is to use a ton of air-slaked lime to the acre, harrowed into the soil after plowing in the manure. This usually overcomes the effect of the acid. The other plan is thoroughly to soak the shavings in stable liquids before putting them into the manure pile, and then permitting these piles to stand until they are thoroughly fermented. Where the manure is put into a pit and watered to keep it moist these shavings are not troublesome, but when hauled from the stable as fast as the manure is made there will be trouble unless lime is freely used in connection with the manure.

Dissolving Bone Fertilizer.

CAN you give me a formula for dissolving bone with potash for a liquid fertilizer? It may not pay, but never mind that. W. G.
Brooklyn, N. Y.

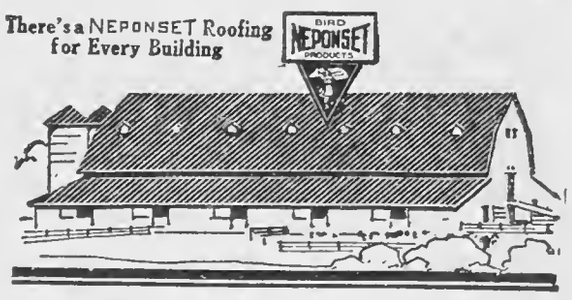
It is good to be able to do things whether they pay or not. A fertilizer chemist and manufacturer gives the following directions:

I have made all kinds of fertilizers for a number of years but this is a new one. The best suggestion that I can give him is to make a box of suitable size of two-inch plank, line this with sheet lead, and in this mix the bone, which previously must be ground up very fine indeed, with ordinary commercial sulphuric acid (50 to 53 degrees Beaumé) at a temperature of 100 to 120 degrees Fahr., in the following proportion: 1,250 pounds of fine ground bone with 750 pounds of sulphuric acid. This should be mixed thoroughly but during the mixing he should tie a handkerchief or wet sponge over his mouth and nose to prevent his inhaling the fumes. This mixture should be allowed to stand about 48 hours and will then have the consistency of a stiff dough or half dried mud. To dry it further he can add 100 pounds more of ground bone or 100 pounds of fine ground carbonate of lime (ground limestone) then if he wishes for potash he can add the potash to the mixture in whatever proportion he desires, using either muriate or sulphate.

This will not however, give him a liquid fertilizer, but perhaps a quantity of this dissolved in water as far as it will would answer.

"ARE you the same man who ate my mince pie last week?" "No, mum. I'll never be th' same man again!"—New York Mail.

There's a NEPONSET Roofing for Every Building



Learn this by heart:—

Only Slowly Made Roofings are Slow to Wear Out

We do not trust to bought felt—the foundation of roofing—we make our own from all-rag fibre, no cheap stock.

Asphaltums, good and bad, *look alike.* Trained chemists select ours and blend them to stand torrid heat and Arctic cold.

We give ample time to tests and inspections at every step of manufacture. That is why Neponset Paroid wears so long, is so truly economical, resists sparks and embers.

Surely send for our ROOF BOOK—free.

NEPONSET
PAROID ROOFING
BIRD & SON (Est. 1795)
704 Neponset Street, East Walpole, Mass.
Also makers of Neponset Shingles, Wall Board and Building Papers

Everjet Elastic Paint

Everjet is made in just one color—a glossy black. It is black because of the high percentage of carbon, and carbon is just what you want in an outdoor paint.

Everjet is elastic and will not become brittle. Best for ready roofings and all exposed metal and woodwork.

This Complete Home Lighting Outfit *only* $14.50

Famous ANN ARBOR SYSTEM Within Reach of All

No more need to put up with poor light in the home. The day of the kerosene lamp is over. You may have perfect light ***right now,*** at little cost, either to install or operate. The wonderful Ann Arbor System has solved the problem.

Brilliant Light in Every Room!

From the very day you install an Ann Arbor System in your home, you can flood every room with a light that is just like daylight. No glare—no eye strain—no dirt—no work—no danger! You couldn't have more convenient light if you lived in the city. The Ann Arbor System is time tested. It is used in thousands of farm homes. It's the most economical light known—cheaper than gas, electricity or kerosene—and absolutely safe.

SPECIAL To introduce this wonderful lighting system to those who are not acquainted with its advantages, we will equip three rooms complete for the trifling sum of $14.50. Think if it! Brilliant, clean, healthful light at this startling, low price. And after it is installed, remember the cost of operation is practically nothing.

$1 Brings It On Free Home Trial

That means just what it says. Your order accompanied by $1.00 first payment brings the outfit by return freight, and after that you have 15 days free trial to satisfy yourself it's all we claim for it. Mail the coupon today—get our beautifully illustrated book "Night Daylight" ***FREE,*** with full particulars about this sensational new offer.

SUPERIOR MFG. COMPANY
Dept. 307 Ann Arbor, Mich.

What You Get for $14.50

Ask about System No. 1. It includes 3 beautiful fixtures for ceiling and wall, and all necessary attachments, such as tank, wires, fittings, etc. Anybody can install it—you can do the work yourself in less than a day. A hammer and screw driver are practically all the tools you need.

Why tolerate dim, unsteady oil light when you can get this modern light at such low cost?

Mail this Coupon Today for SPECIAL OFFER

SUPERIOR MFG. COMPANY
Dept. 307
ANN ARBOR, MICH.

Please send me your free booklet "Night Daylight," and full particulars about your $14.50 lighting system and special new free trial plan.

Trouble With Young Turkeys.

IS the feeding of wild buckwheat harmful to young turkeys? My growing stock, which until they had attained pigeon size, had never been ailing, is dying fast. I find that lungs bear whitish spots, mostly round and some half an inch across; gizzards almost filled with undigested wild buckwheat seed, a small percentage of which is contained in the feed I get here. I have cut out this feed and secured wheat, which I am now feeding in connection with crumbly bran mash, sour milk, and bone meal. C. B.

Alabama.

I do not know of wild buckwheat seed proving fatal to turkeys, and think it more probable that your young turkeys are dying from some infection, very likely blackhead. In this disease, which is prevalent over the greater part of the country, the liver and "blind gut" of the intestines are found studded with such spots as you describe in the lungs and the latter organs may also contain them. Tuberculosis of the lungs would also produce such spots, but this is comparatively rare in fowls, the intestines being usually the seat of tuberculosis in feathered animals. There is no known cure for blackhead. The disease most frequently makes its appearance when the turkeys are from one-third to one-half grown; they become sleepy, stupid, emanciated, lag behind the rest of the flock and in a few days from the time they are observed to be markedly affected are found dead. This disease has practically put an end to turkey raising on a large scale in some of the Northern States, notably Rhode Island, which was once famous for its turkeys. Another infectious disease, aspergillosis, would also produce tubercles, such as you describe, in the lungs, but this also is comparatively rare.

M. B. D.

Ailing Chicks; Broody Hens; Soft Yolks.

I HATCHED, under a hen, seven chicks. Two did not become larger or grow new feathers. They refused to eat. We fed them every day by opening their mouths and dropping in sour milk with a medicine dropper and sometimes a little chick feed. After they were four or five days old we found one louse on each, but after that they seemed no better. One died on eighth day. The other still lives and slowly gains but is even now fed by hand. I would like to know the cause and prevention. 2. What is the best way to "break up" broody hens. 3. I have a neighbor who occasionally finds an egg with yolk and white together, resembling a rotten egg. The eggs are collected regular and are certainly fresh when found in this condition. Will you tell me how the hen laying these eggs can be found also the cause and prevention. H. F. S.

1. These chicks that did not develop properly were lacking in vigor, very likely as the result of the same lack in one or both parents. Such chicks should be killed for the good of the race. Only vigorous chicks are worth raising.

2. Place broody hens in a separate compartment, with no nests or place to make them. Water copiously, feed sparingly and wait patiently. A few days of isolation will usually "break up" Leghorns; some of the larger breeds require isolation, moral suasion, starvation, and finally decapitation.

3. These hens laying occasional eggs with soft yolks should have green stuff, including clover, if possible, animal food of some kind and as much range as possible. If one hen only is responsible, she is probably "out of condition" and may recover. I know of no way of detecting her without trap-nesting and breaking each egg laid until she is found.

M. B. D.

Trouble With Hatching.

I SET an incubator with 120 hen eggs and 38 duck eggs. I hatched out 5 chickens. The rest of the eggs formed chicks, all but three which were rotten. The incubator was kept at 102 degrees and the eggs were turned and sprinkled regularly. What was the trouble? Was it in having the hens and duck eggs set together in the incubator? 2. How many cockerels should there be in a flock of 60 hens? M.

New York.

1. Hen and duck eggs should not be incubated together, but you ran this machine at too low a temperature if you kept it at 102 degrees throughout the hatch. An incubator should be run at the temperature advised by the manufacturers, which is usually from 102 to 103 during the first week, and at 103, or a little above, for the remainder of the time. 2. Sixty hens of the smaller breeds should have two vigorous cockerels with them, and the same number of hens of the larger varieties would better have three, though two might be sufficient.

M. B. D.

Hens With Inflamed Eyes.

SEVERAL hens are taken with a running from the eye; it swells up and matter seems to force out. We seem unable to cure them. What is the trouble? W. L. B.

New York.

This is a catarrhal disease of the eye usually connected with a similar inflammation of the lining membrane of the nostrils, which membrane is continuous with that of the eyeball. It is due to exposure to dampness, drafts, etc., and in some cases is infectious spreading from one fowl to another. It is also one of the preliminary symptoms of roup. In simple inflammation of the eye, or conjunctivitis, is is usually sufficient to place the affected fowls by themselves in warm dry quarters, add permanganate of potash crystals, a teaspoonful to the quart, to their drinking water, and dip their heads into the same solution. If the disease shows a marked tendency to spread, promptly isolate all affected fowls, disinfect their quarters and utensils, use the permanganate of potash solution freely, and burn or bury any fowls that die from the disease. Simple inflammation shows a tendency to recover, the contagious or roupy form should be dealt with vigorously until eradicated from the flock; isolation and disinfection being the chief remedial measures. M. B. D.

Sprinkling Hatching Eggs.

I SET a hen and in the required length of time for her to hatch I could hear chicks in the shell, but they did not hatch. Some told me to sprinkle eggs with water, but I was doubtful as to results, and did not. Should I have sprinkled the eggs or not? N. T. B.

New York.

It is not necessary to sprinkle eggs set under hens, and the fact that the eggs did not hatch shows only that they did not contain germs of sufficient vitality to complete the process of development and emerge from the shell. This is pre-supposing of course, that the hen attended properly to her job. The writer recently hatched 44 chicks from 48 eggs set in crates of perfectly dry hay on a board floor over a basement. Not much chance for outside moisture to have reached them, and with the additional handicap of having been shipped several hundred miles by express. M. B. D.

English Leghorns Bred in America.

REGARDING Mr. Orr's query on page 810 as whether the progeny of Mr. Barron's birds can keep up the good work for American breeders, I wish to say I imported a pen of Mr. Barron's White Leghorns in March, 1913, the male in this pen being a brother to the pen that won at Storrs last year, the birds there being sisters. Ten daughters of the pen I imported are in the Missouri egg-laying contest, being pen 67. These 10 pullets were not especially selected. I took the 10 earliest I had, and they were not mature enough by two months. However, in April the 10 laid 240 eggs, taking third place in the contest for the month. In May they laid 227 eggs. In the April report pullet No. 675 had laid 116 eggs in five months, only three pullets in the entire contest laying more. These are all pure Barron strain, raised by me here in Missouri. I have been breeding pure-bred poultry for 13 years and have taken hundreds of ribbons at the smaller shows, and some at the larger ones in this State, and I find that the Barron line will breed as true to their type as any line of show birds I have ever handled will to standard type.

Mr. Barron's birds will not all produce like his winning pens last year, but they are bred right to produce, and I believe will prove a success under ordinary conditions in this country. If they had to have ideal conditions and be pampered and petted to lay well, they would not suit me, but under ordinary farm treatment they have laid better than any flock I have ever owned, and are giving me satisfaction. J. R. MOONEY.

EGGS AND TRAP NESTS.—George A. Cosgrove asked about "A Chicken Man's Honor." Why not sell eggs on understanding that they be properly tested, and if found infertile, returned to him prepaid for inspection, then if claim is proven, send prepaid for nothing or at one-half price a new setting. This system balances and seems fair to both sides. Long ago a woman asked how to make a trap-nest substitute. Divide the pen with wire or other partition. In this partition set nests which can be entered from one side only and can be left from the opposite side only. Leaving feed in litter both sides and water and dry mash so as to be reached from both sides. The hens go through nests to opposite side of partition. At convenient times count eggs in nests, hens who have passed through nests and you can tell which hens laid the eggs, but not which hen laid any particular egg. Once in a while a hen will go through a nest without paying toll, but generally—nine times out of ten—the person who is too busy to trap-nest properly can tell which hens do lay and of course they should be banded, note made of their number, and a pretty satisfactory record obtained.

Connecticut. GEORGE E. CROSBY JR.

BUFFALO MARKETS.

THE strawberry season is about ended. It has been only moderate as to supply, with prices rather higher than usual, really desirable fruit seldom selling for less than 10 cents a quart. More pains than usual has been taken to keep the fruit in marketable condition. Some city grocers have made a reputation for refusing to handle inferior fruit and in this way they have been able to compete with the market stall people, who will often offer fruit that looks well on top, but is soft below. As usual the local crop was not sold for any less than earlier southern fruit. Red raspberries are now coming in at 15 to 18 cents a quart, retail. Some peaches have appeared at fair prices and it is said that the failure of the home crop will not cut out the supply. Potatoes are higher. Retailers ask $1.75 for new southern, which are now crowding out the Bermudas. Dealers pay $4.85 for new Maryland Eastern Shore per barrel. Dry weather is holding back the late home crop. Cabbage and onions are still high. Small new home-grown cabbage retails at five cents and southern to retailers is $1.50 per crate. California onions are quoted at $3.85 per crate. The home-grown green supply is larger, retailing at three bunches for 10 cents, as are beets and carrots. Peas are now going to canning factories in quantity, a fair crop. The price to retailers is $2 to $2.50 per bag. Fine cucumbers retail at two for five cents or 50 cents a dozen to dealers, tomatoes $2 per box. String beans are five cents a quart or $2 per hamper. Cherries are in fair supply at 10 to 12 cents a quart or 40 cents a six-pound basket. Blackberries are temporarily out, but blueberries are arriving, retailing at 14 cents a quart; blackberries 10 to 12 cents; gooseberries 10 cents. There are new southern apples at $2 per hamper and a few cold-storage of fine appearance at about two cents each, though buyers say they are fast losing their taste. Melons are becoming plenty, small muskmelons retailing at two for five cents or $2.50 per crate wholesale and watermelons at 40 cents each retail and 30 cents wholesale. There are no squashes yet. Butter is in light demand at former prices. The highest retail price is 30 cents, with extra creamery prints touching 29 cents wholesale, down to 14 cents for all sorts of poor butter. Margarine is not regularly quoted, but Chicago brands sell at about 10 cents under butter. Eggs are strong and active, the wholesale range being 21 to 25 cents, with best fresh retailing at 25 to 27 cents. Poultry is scarce; wholesale prices are 15 to 17 cents for live turkey and 21 to 22 for dressed; fancy fowl, 16 to 17 cents, live; 17 to 18 cents dressed. Ducks are 14 to 16 cents live; dressed Spring 17 to 18 cents per pound. Fancy broiler chickens are down to 22 to 23 cents for 1½ to two pounds and two cents lower for heavier. J. W. C.

PEACHES are a total failure in this section this year. Apples are looking fine and promise about one-half or a little more of a crop; pears, one-half crop; cherries are a big crop here, prices low. Some hay crops are very light here. Wheat is looking fairly well. Oats and corn went in so late they are very backward but are growing fast because the recent nice rains. Considerable cabbage has been planted in this vicinity and is looking well. W. D. S.

Newfane, N. Y.

LONG ISLAND is looking its best and everything favorable for one of the bumper years. I just finished a tour out as far as Shelter Island on one side and back to New York the other and also through the center. Planting of potatoes seems about normal, and a good crop is in sight. Cauliflower planting is about over and that crop looks fine. The cabbage seed crop is bound to be good. The truck farmers on the west end have got the goods and they seem to get the price this year. It is gratifying to see in the sands of the central part how they are displacing the scrub pine with fine fruit trees and good crops. To make a little study of what one sees, in going over the central part of the Island he would be led to believe that the thousands of idle acres could be transformed into useful farms. But the real estate shark has killed the prospect for the farms. He can pay a high figure for cheap land when he buys and sells on paper. So we are bound to keep the idle acres for years to come. T. T.

For a Heavy Summer Growth

—of any legume—alfalfa, clover, vetch, peas, beans, etc.—there is nothing like inoculating the seed with

Ferguson's NITROGEN BACTERIA

The Bacteria gather Nitrogen—the plant food most soils lack—from the air, and store it on the roots of the plants in such quantities that only a part is used and the rest left to enrich the soil. The same bottle of Ferguson's contains all the varieties of Bacteria necessary for the inoculation of any legume.

This is no experiment, as hundreds of letters from users prove. You can do what they have done.

Costs only a fraction as much as the best commercial fertilizer

Quarter-acre quantity, 50c.; 1 acre, $2; 5 acres, $9. Let us explain why you need Nitrogen Bacteria and why Ferguson's is best. Write for special booklet N—free.

COSTS LESS TO KEEP IN REPAIR THAN ANY OTHER DIGGER

Adjustable in every necessary way and easily controlled.

***Digging Potatoes with an* IRON AGE**

is like finding money because the work is so easily and economically done. You can dig in one hour all that a market wagon can carry to town. Saves time, saves labor, gets all the potatoes, helps you get to an early market when the price is right.

Four styles from which to choose the one that suits your conditions best. You pay for, and your horses draw, only what you need.

We have been making Diggers 10 years and know what to build for this work. Our booklet tells the whole story in an understandable way. May we send it?

BATEMAN M'F'G CO.
Box 102 D *Grenloch, N. J.*

Grade for Open Ditch.

WILL a grade of one foot per 1,000 feet be enough for an open ditch? E. J.

If this four-foot ditch will run full in flood time a grade of one foot per thousand would be better than a heavier grade, because of the erosion of banks. But if the ditch will never run more than half full a heavier grade would help more toward making it partially self cleaning. Velocity of water is so accelerated by volume and depth that a mild running shallow stream is changed to a rushing torrent when at a flood depth of four feet. In open ditch construction we find natural limitations to grade that we can only partially adjust—hence many drainage canals as light as a foot to the mile. J. F. V. S.

Driving Off Rabbits.

CAN you give an effective remedy against rabbits, that eat the young blossoms and tender leaves from the top or tips of growing bush snap beans? Would spraying with lime-sulphur, or with sulphur alone, cause a disagreeable taste to these young shoots, or would a trap row, not to be marketed, sprayed with an arsenical poison reduce the marauders? R. W. C.
Pemberton, N. J.

We assume this refers to bean culture on a large scale. We doubt if spraying will prove a complete remedy. Weak solutions of some tobacco mixture would probably be better than lime-sulphur, though we have never tried either for this purpose. This is a case to submit to our readers for experience. If we had a large acreage and were greatly troubled in this way we should use a number of smart and noisy little dogs—keeping them in the field as much as possible, and employ some good marksman to shoot the rabbits.

Extent of Immigration.

COULD you tell me how many immigrants came into this country last year, and how much money each was required to have? W. A. M.
Ohio.

The report of the Commissioner of Immigrations shows that during 1913 there were 1,197,892 alien immigrants admitted to this country. The greater portion arrived at New York—892,653. The amount of money an alien must have is not fixed by law. The authorities use their jndgment regarding this, the points to be considered being that he shall have enough to provide for his reasonable wants and those dependent on him until he is likely to get work. When bound for an interior point he must have his railroad ticket or money enough to buy it.

Questions About Fish Culture.

JUST at present the "Fish Law" is not available. When is the open season for pike, pickerel and black bass. 2. In stocking a pond would the above game fish destroy such fish as bullheads, yellow perch and sunfish? The pond is one acre in size; half is nine feet deep, the other half gradually shallow. Bottom is muck and sandy, fed by numerous springs, and plenty of shade. 3. Is the mud turtle harmful to fish. If not, is it of any value? H. K.
Ulster Co., N. Y.

1. The "Fish Law" is still not available, so I cannot tell about the special exceptions, but the general season is open on all the fish named and will remain so until long after we should all receive copies of the new law. It is impossible to say when we *will* see the new law in print.

2. These fish would eat all the bullheads, yellow perch or sunfish they could catch and swallow, but would not be likely to destroy them all unless the pond was much overstocked. If "pike and pickerel" is used in the same sense as in the published game laws of New York State, these fish should do well in the pond described if the water is shallow and muddy with a growth of marsh plants at some part of the edge where they can spawn. Large-mouth black bass will also do well under these conditions but, Small-mouth bass need cooler water and gravelly bottom near shore where they can lay their eggs.

3. The common painted tortoise is probably the one meant by "mud turtle." If so, they are not likely to be harmful to fish as they would catch very few that were not diseased or injured. In Maryland and farther south all turtles are eaten more or less if they are large enough and do not have an unpleasant odor. This turtle seldom gets more than six inches long (length of upper shell) and is seldom seen in the markets of Washington and never, so far as I know in New York. If the "mud turtle" is one of the larger ones, known variously as "map turtles" or "sliders" there is a small demand, increasing southward, but the price is never so high as for the snapping turtle or terrapin.

The most important points to notice in deciding what fish to put into a pond are (1) the temperature at surface and bottom in the warmest weather of Summer. (2) The character of the bottom; whether stony, gravelly, sandy, muddy or very soft mud. (3) The character and amount of the water flowing in and out. Some failures to introduce fish into ponds have been apparently due to the fact that the water came from peat swamps and was too acid. In some experiments made at Washington it was found impossible to keep fish alive in water showing an acid reaction. ALFRED C. WEED.
Wayne County, N. Y.

Barley, Cow Peas or Soy Beans.

SHOULD I sow barley on last year's corn ground for plowing under next September, for seeding to grass, or sow Cow peas or Soy beans for the same purpose, and if either of the latter what would be the value above barley?
Connecticut. J. A. G.

It would not pay you to sow barley at this season as a cover crop. Barley is a plant for cooler weather. It would make a fair growth in the Fall, but not during the Summer. Either cow peas or Soy beans would be better, but a simple crop would be buckwheat with two or three pecks of field beans seeded with it per acre. Put that in broadcast, and that would make a fair growth which can be plowed under in September, so as to benefit the soil.

A Drainage Question.

A CERTAIN man states that one can ditch from a low wet spot in a field to a higher. He states that the hill will draw the water. What do you think about that? I have a wet spot in my field I would like to drain out. J. P. A.

We think that young man who expects that a hill will draw water through a ditch away from a low place will have his labor for his pains, unless he puts a pump of strong power on the hill and uses it to pump the water. There is nothing to such a proposition.

No Friend of a Cat.

IT is very seldom that I disagree with anything you publish but your advice in a recent issue as to what to do for a sick cat, instead of medical treatment, should have been either the ax or bullet.—With me this would apply to the majority of cats, sick or well. A good mouse-trap, with but little trouble, well placed, beats the cat 10 to one, and does not spread contagious diseases, neither cut short the life of the beneficial bird or chick.
Iowa. P. A. H.

Sweetening Cistern Water.

HOW can we sweeten a rain water cistern when the water has an unpleasant smell, and is not agreeable as water for bathing and for watering stock on the farm? J. D. M.
Albany, N. Y.

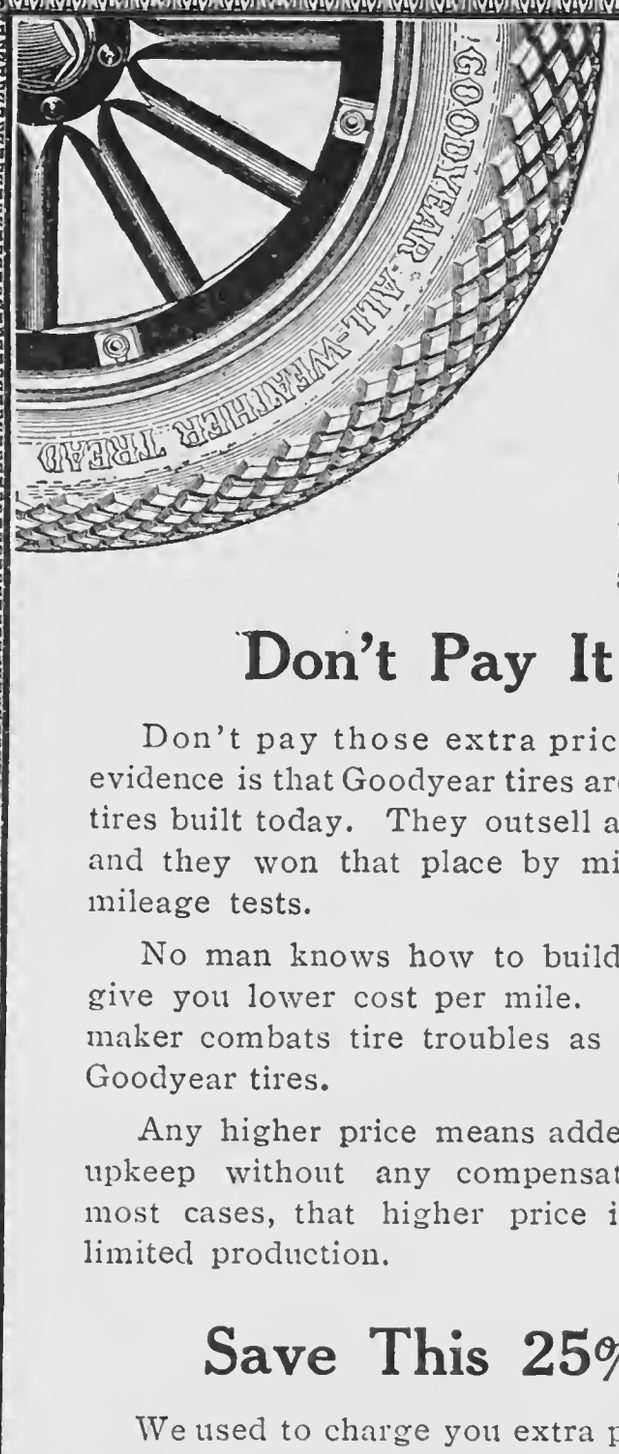
Cistern water which has a foul odor from being kept from the air, but is not polluted by foreign matter, may be sweetened by aerating it. The cistern should be opened to the air and the water agitated very much as the cream in a churn is during the operation of churning. Underground cisterns which cannot be adequately ventilated are subject to foul odors from the contained water becoming stale. M. B. D.

Exterminating Bats.

WHAT can be done to get rid of bats? They live in the attic by the hundreds and make it so foul that nothing can be kept there. L. S.
Sullivan Co., N. Y.

We have had no personal experience with bats. Can any reader tell us?

"HE'S a self-made man." "I know. He surely made a mistake in not consulting an expert."—Detroit Free Press.



One-Third More for Tires

16 makes of tires now sell for more than Goodyear prices. Half of them cost about one-third more. As compared with them, Goodyears save you 25 per cent in original cost alone.

Don't Pay It

Don't pay those extra prices. The evidence is that Goodyear tires are the best tires built today. They outsell any other, and they won that place by millions of mileage tests.

No man knows how to build a tire to give you lower cost per mile. No other maker combats tire troubles as we do in Goodyear tires.

Any higher price means added cost of upkeep without any compensation. In most cases, that higher price is due to limited production.

Save This 25%

We used to charge you extra prices for Goodyear No-Rim-Cut tires. That was because of exclusive, costly features.

Those tires are built the same today. They have the same exclusive features. But we now build ten tires where we then built one. We have modern equipment, new factory efficiency. Our prices came down as our costs came down. They are half what they used to be.

Accept this saving. It is one of our greatest accomplishments. The price of the leading tire of the world is all that you should pay.

Exclusive Features

These four features of No-Rim-Cut tires are found in no others at any price:

Our No-Rim-Cut feature, which wipes out rim-cutting completely.

Our "On-Air" cure, which saves all the countless blow-outs due to wrinkled fabric. This one exclusive feature adds to our tire cost $1,500 daily.

Our patent method for combating tread separation. It reduces this danger by 60 per cent.

Our All-Weather tread—our double-thick, resistless anti-skid which, because of its flatness, runs as smoothly as a plain tread.

Note that these are all exclusive Goodyear features. No other tire offers one of them. Every year they are saving our tire users many millions of dollars.

You will get them all, at the Goodyear price, if you ask your dealer for No-Rim-Cut tires. Any dealer can get them quickly if your size is not in stock.

Hope Farm Notes

A PATCH-WORK DAY.

PART II.

PLANTING THE POTATOES.—Hitch yourself to an Acme harrow with a healthy man sitting on it on a sultry, windless day, and you may imagine how Tom and Broker looked at me everytime they passed. I sat on the wheelbarrow at one end of the field cutting seed—the two little girls "helping" by passing the potatoes. The Italian army gladly raised the siege of asparagus, untied a few knots in their backs and came to the rescue of my theory. We ran two lines of twine across the field—the rows three feet apart. One man followed each line—the other between dropped seed for both. With a blow from a large hoe a hole or cut was made about four inches deep down into the buried sod. The seed was dropped into this, covered with soil and firmed by patting down with the hoe. As we cultivate I expect to hill up gradually. You may call this slow and tedious planting, but under all the circumstances I think it the best way to plant at this season. You would be surprised too if you could see how rapidly the men put the seed in after they were organized. I purposely cut the seed in large pieces, usually cutting a good-sized tuber in halves. We have often tried late planting before, but never with much success except once, when we used seed which was dug in Florida during April and shipped here. This gave us a fair crop of medium-sized tubers. I have always believed that in order to do well late potatoes must be put into damp soil, rich in organic matter, in a cool moist season—planted about as we put them in. Now having a chance to try my theory let us wait and see.

CLEARING UP.—There were still some 90 minutes of the day's work when the potatoes were in. The Italians went at the asparagus once more, and the little girls begged me to show them how to pot strawberry plants. So armed with a hoe, a trowel and a string of pots, we hunted through the newly set Marshalls for runners. Down in the dirt the little girls soon leaned to fill the pot with fine soil, sink it in the ground, bringing the roots of the runner over it and fasten it down with a little stone. I went ahead with a hoe and cleaned out the weeds. The girls were having a glorious time, fat and wet and dirty, when a stern figure with waving arms appeared in the barnyard.

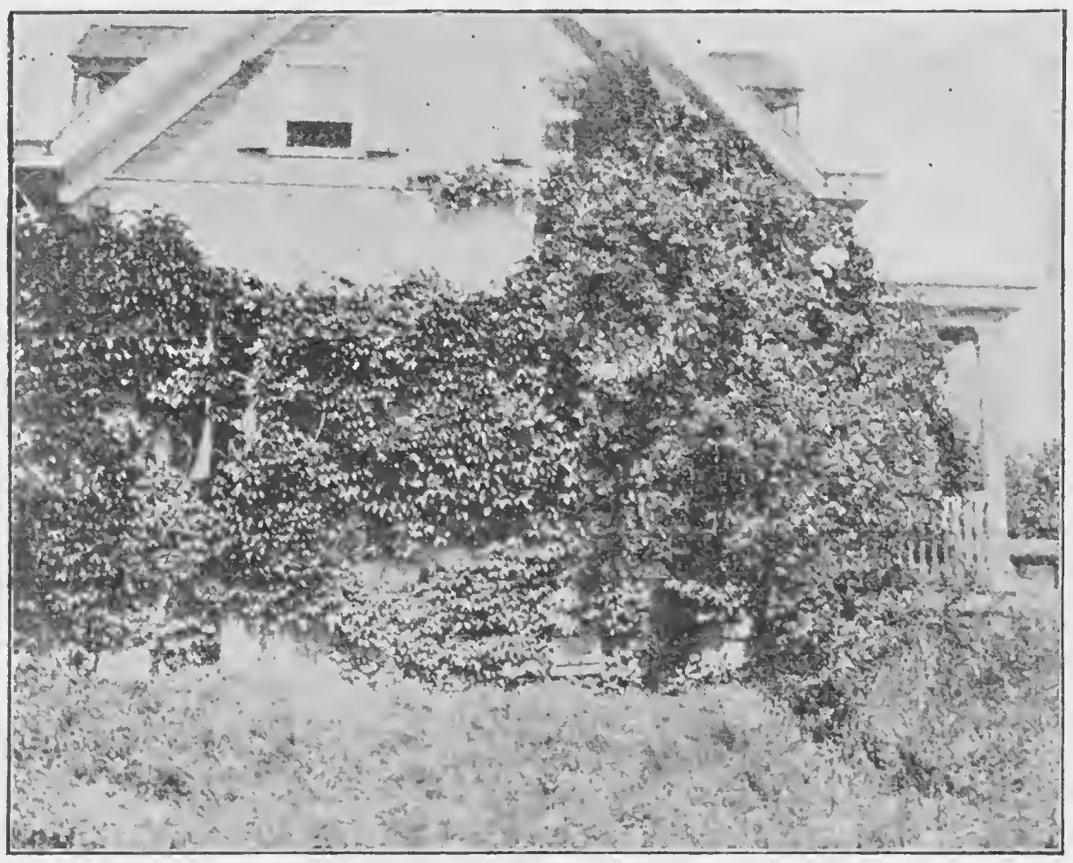
"Oh, ain't it awful!"

"We gotta go an' have our bath!"

Off they trotted, leaving me to finish the pots. The boys came, driving Bob into the yard. Every berry and pea had been sold. They even had to pick five quarts more for supper. I suppose I might have joined the Italians at their knee service, but somehow of late years my petitions to Nature seem a little more heartfelt when delivered standing at the end of a hoe. So I started in to clear up our potted plant nursery. But a sort of monitor on my back told me I had worked enough. Off in the west a small cloud was forming. It was even larger than a man's hand, and I confess that it formed a good excuse to see if supper was not nearly ready. It was, and in due time we lined up once more—as the Italians marched off with their share of the spoils.

END OF THE DAY.—The little girls were upstairs, pretending to be asleep if Mother came that way, but very much awake when I looked into the room. After a satisfying meal of baked beans and strawberries a man may well walk about and give a last look to the farm situation. Another of these mean little showers was forming in the west. I estimated the currant crop as nearly as possible—the fruit is red and picking will begin Monday. Then I found a dozen peach trees left from the last cultivating where the weeds have grown waist high. Twenty minutes with the scythe changed them from suckers to succorers. Then a spatter of rain drove us all to the front porch. There we sat and watched the belated automobiles rushing by on their way home. Of course they exceeded the speed limit, but one could forgive them on the homeward trip. It grew cooler as the damp darkness came upon us and the wind began moving the branches of the trees as night finally threw her blanket around the farm house. It was an untimely and unnecessary thing on a June night, but a little blaze in the fireplace made the night a little more cheerful. The hay was still wet and the grass is growing in the cornfields, and those berries in the wet, thick vines will be ruined if this keeps on. It was surely a patchwork day, but we did our best, and as the house grew still the Hope Farm man nodded off over his book before the fire.

POOR HAY.—This is the worst season for haying I have ever known in this country. Usually by the Fourth of July we have most of our hay in the barn or ready to house. This year only one load was under cover. There were three or four more on the ground waiting for one good hay day. The constant showers have prevented cutting and curing and the grass is old and seedy. It looks like a crop of poor discolored hay for us. The second crop will be heavy and this is a good season for top-dressing the meadows after the first cutting is off. The soil is moist now and it seems as if the showers are to continue, so that soluble chemicals put right on after the hay is off the field will whip up another growth and give some good hay. This is also a good season for such crops as Japanese millet, corn fodder or sorghum, and there ought to be a good chance to grow substitutes even if the hay crop is poor.



VINES AT THE END OF THE HOPE FARM HOUSE. FIG. 387.

"ORNAMENTS."—Our experiment at landscape gardening is turning out very satisfactory. This moist season has given the shrubs and trees a great start and as they grow they change the entire appearance of the place. The picture at Fig. 387 shows the eastern end of our old stone house. This house is jammed up close to the road and when this road was finally stoned, several feet were blasted out so that the house now stands on a rocky ledge. When we came here I planted Boston ivy at the end of this house and when THE R. N.-Y. sent out climbing roses to its readers we planted one of each and let them grow as they would. The great bush at the right is Crimson Rambler, about the largest one I have ever seen. At the left hand corner is Ruby Queen. This runs for many feet around the side of the house. When these roses are in bloom they present a magnificent mass of color and attract more attention than anything else for miles along the road. This old house dates back to before the Revolution—one of the old timers in this section. It is only occupied now for sleeping but we lived in it for some years when we first came to the farm.

POTATOES.—Our crop never looked better on July 4. It is all planted between the rows of fruit except that last planting on the old strawberry sod. The best field is at the back of the farm on soil which, so far as I can tell, never grew potatoes before. We started a young apple orchard there and this Spring plowed under a heavy growth of rye. Crimson clover grew well last Fall but most of it was killed out this Spring. The rye was all tucked under and packed down by weighting the Cutaway and then the Acme. As far as possible the seed pieces were put right down into the rye without ripping it out and the fertilizer was scattered along the furrows. There has been abundant moisture and as the result of this handling the plants of Irish Cobbler stood over two feet high by July 4 with a rich green and little potatoes as large as walnuts. Considering that these potatoes were not planted until late in May this suits us well. The field is very weedy. The potatoes were well cultivated and hoed—then a small plow was used to throw furrows from each side so as to smother out the next crop of weeds and grass. Not a bug has appeared in this field yet—in fact the bug crop is lighter this year than I have ever known before.

STRAWBERRIES.—On the Fourth of July we picked about eight quarts of Marshalls. This was 35 days from the first picking and it looked like five days more. This is, of course, an unusual season but I doubt if any other variety can equal Marshall for long continued fruiting. If it were only a heavier yielder it would stand at the head for rich heavy soil. It is a flat failure on the lighter soils or with poor culture. Our Spring set beds are looking well. Runners are starting and we are putting in the pots quite freely. I notice some large stories in the papers about yields from potted plants. I think they are largely guff, for the man who expects to grow a full crop next Spring from a potted plant set this Summer will be sadly disappointed. One case is reported to us where 200 potted Marshalls planted last August gave nearly a crate this year. These plants had the finest of care and the season was favorable. I would not guarantee the average purchaser of 200 plants 10 quarts, but he would have a bed well established and get a good outfit of plants. We have had a little experiment with lime and strawberries. In the middle of one of our plantings our folks burned a big brush pile and scattered the ashes. The field was all manured and plowed alike. Now a man with but one inferior eye could see the difference. Where the ashes were scattered the plants are dwarfed and some of them have already died. Outside of this space the plants are large and fine. There may have been something beside the lime in the ashes to cause this but I am satisfied that wood ashes and lime should never be put on berries. H. W. C.

$2.25 WORTH OF ROCK PHOSPHATE PRODUCED 25 BUSHELS OF WHEAT

At these figures an Illinois Farmer secured increased wheat yields at a cost of less than 10c per bushel, and three-fourths of the Phosphorus remains to be used by future crops.

Write us for prices on Daybreak Finely Ground Rock Phosphate, and learn how other farmers are building up their soils and their bank accounts.

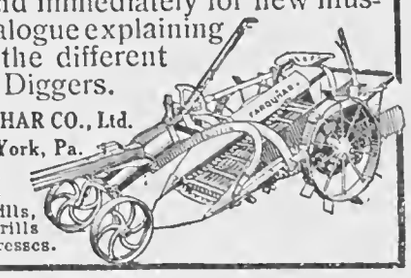
Get All Your Potatoes

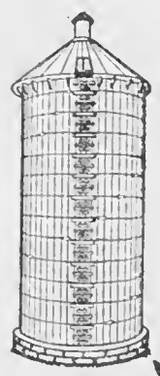
The Farquhar Elevator Potato Digger does the work of a crew of men. It frees all the potatoes from the soil and puts them on top ready for sacking. If you raise potatoes for profit, it will pay you to send immediately for new illustrated catalogue explaining all about the different Farquhar Diggers.

A. B. FARQUHAR CO., Ltd.
Box 230, York, Pa.

We also manufacture Engines, Saw-mills, Threshers, Drills and Cider Presses.



DIRIGO SILOS



Are GOOD Silos. It has been our persistent purpose for fourteen years to make a perfect Silo. Every DIRIGO SILO is sold by mail. We want to mail a catalog and price list to every farmer who keeps stock. A postal card will bring our Special Early Order Prices delivered at your nearest station. Prompt shipments.

STEVENS TANK & TOWER CO.
AUBURN, MAINE

E. Frank Coe Fertilizers

1857 THE BUSINESS FARMERS' STANDARD FOR OVER FIFTY-FIVE YEARS 1914

Plan Now For Midsummer Seeding to Alfalfa Fall Seeding to Wheat, Rye and Grass

GIVE your Alfalfa the abundance of Phosphoric Acid and Potash that it needs, but remember also that while Alfalfa takes its Nitrogen from the air, *after it is well established* a moderate quantity of quickly available nitrogen is necessary to give the young plants a vigorous start before the root nodules develop.

In **E. Frank Coe Fertilizers** you get the right proportions and right kinds of plant food for your Alfalfa.

When seeding down to Wheat or Rye with grass, remember that you must supply sufficient plant food for two crops; otherwise your Wheat or Rye may be a success but your grass crop may be a failure.

Be sure therefore, to use fertilizers containing sufficient plant food to give Wheat or Rye and grass a vigorous start this Fall and also containing plant food that will become available next Spring and Summer, thus insuring profitable results from both crops.

Seeding to permanent mowings is best done late in August or early in September, without either Wheat or Rye. In this case use a heavier application of seed and a generous application of **E. Frank Coe Fertilizers.**

We have many different grades and kinds of **E. Frank Coe Fertilizers** adapted to every variation of soil and local conditions. If you will advise us about your soil and crops we will give you our honest opinion as to which fertilizers will give you best results.

You ought to read our booklet "Seeding to Grass and Clover." A copy is yours for the asking, without charge, of course.

THE COE-MORTIMER COMPANY, 51 Chambers St., New York City

Ruralisms

Transplanting Mountain Laurel.

WE have quantities of beautiful mountain laurel in our woods. Can you tell us when to put it out in clusters and hedges about the farmhouse? We have made some grow, but haven't been very successful. C. E. U.
Shelton, Conn.

Mountain laurel (Kalmia) should be transplanted in Spring or early Fall. It is wise to mulch it the first season; this protects the roots from both drying sun and frost. This shrub prefers a shady situation, but will grow in a sunny place if there is abundant moisture. It is often found in swamps, though it grows abundantly in hillside or mountain woods. It dislikes clay or limestone soils, and is at its best in peat, sand or loam.

Experience With Small Fruits.

THE strawberry season has come and gone. I would be glad to hear your report on the Joe, as you said you had ventured in setting out that variety. With me it is a plump failure; spreads out on the ground like a purslane plant, long pointed no-flavored small berries, shaped like the old Parker Earle, but nothing to compare with that good old kind under favorable conditions. Of Helen Davis, early, one trial is enough.

The raspberries are now coming on, Plum Farmer, Hoosier and Winfield. I have some new grapes (with me) coming into bearing this year and they all look fine now; Lutie, Campbell's Early, Brilliant, Barry, Herbert-Salem, Bacchus, Lucille, Brighton. Peaches a full crop; poor apple prospects; Corn looking well; rye harvest just began, all Fall grain fair; oats and Spring wheat rather short; hay crop one half, but this is more locally than generally, as it has been too dry in this county. A. J. MASTERS.
Iowa.

R. N.-Y.—Joe seems promising to us after a brief trial. It is not fair to judge a variety entirely by the behavior of Spring set plants. We were cautioned about planting Joe on rich soil which would be suitable for Marshall, but to put it on light soil. It makes good-sized berries of fair flavor and we shall try it further as a partner for Marshall.

Onions.

HAVE you ever succeeded in growing large onions of the Bermuda and Prizetaker varieties by planting them outdoors in the Autumn, or have what you raised of these onions, planted in the Fall, been small? 2. Have you ever been able to destroy grass which has become well started in an asparagus bed, and have you used salt to destroy the grass? B. R.
Maryland.

1. I have never transplanted the Bermuda onions, but have grown fine ones direct from the seed sown very early in Spring. Seed of the Prizetaker, Denia and Giant Gibraltar sown early in September here, and transplanted as soon as the plants are about the size of a lead pencil, will make large onions the following Summer. But I have made finer ones by sowing the seed in January in a cold frame, and transplanting them later into well-prepared soil. For the earliest green onions I plant sets of the Norfolk Queen, a different onion from the Queen of the Northern catalogues, in September. These are usually ready for the table here in late February. At the same time in September I plant sets of the Yellow Potato onion, and in May we can use the offsets of these for green onions, the Queen having been used up. The main bulb of the Potato onion is left to ripen, and they make fine large onions. I sow the seed of the Norfolk Queen very thickly in April and a single row 40 feet long makes me all the sets I need for the Autumn planting. I never plant sets of any sort for ripe onions except of the Yellow Potato onion. There is nothing more easily transplanted than a young seedling onion. I pinch the roots slightly and the top too and set in very shallow furrows. For a substitute for green onions in the early Winter I sow seed of the leek early in Spring and transplant them in July into open furrows, and draw the earth to them as they grow and finally hill a little so that we get a long white shank. Being perfectly hardy, these are left in Winter where they grew, along with the salsify, parsnips and late carrots, none of which we lift here. 2. I never had to clean an asparagus bed well set in grass, because I never let mine get in that condition. I keep the asparagus cleanly cultivated all the season through, and make the heaviest fertilization after cutting has ceased, so as to get a strong growth of crowns for the next season. I never use salt as salt, but do use kainit freely, and that carries a good deal of salt. You will never need to use salt to kill grass if you keep the crop well cultivated all the time.
Maryland. W. F. MASSEY.

Hawkweed or Paintbrush.

I AM taking so many papers and magazines that I had concluded to stop THE R. N.-Y. and then I made up mind that I could not get along without it, and I would stop some other paper instead. Enclosed find a flower I picked in my meadow. Please tell me the name of it and how to stop it spreading over the farm. Is it poisonous? J. L. B.
Bennington, Vt.

The plant sent is Orange hawkweed or paintbrush, Hieracium aurantiacum. It is a terrible perennial weed, damaging pastures in many localities. It spreads by seeds and creeping rootstocks. The roots are near the surface, so plowing and surface cultivation will destroy it. Infested pastures should be broken up and given a short rotation of hoed crops. On upland pastures which cannot be plowed Prof. Jones of Burlington, Vt., advises broadcasting dry salt over the patches. 18 pounds to the square rod (1½ ton to the acre). We have never heard that it possesses any poisonous qualities. Another Hieracium, the rattlesnake weed, H. venosum, is said to possess some medicinal qualities.

Grass Under Trees.

WHAT can I do to make the grass grow under my trees? Last Fall I dug up the soil about them and filled it full of organic matter and this Spring sowed it with shady lawn seed. It came up in great shape and has been cut too or three times, but it is thin and don't seem to make a sod. I have used nitrate of soda and last Fall and this Spring applied a liberal amount of bone meal. Can you suggest something?
Manayunk, Pa. J. H. J.

It requires time for the growing of turf from grass seed. Under very favorable conditions a fairly good sod will be formed in the first year, but as a rule it requires the second season's growth to make a good turf and under unfavorable conditions a longer period will be required. In dense shade it is sometimes quite out of the question to get a good sod formation. It would seem there had been sufficient fertilizer applied this season. At the beginning of Winter cover the grass lightly with partially decayed rough manure, this will afford Winter protection and the leechings of the manure will be quite a stimulant to the grass in the following Spring and Summer, and will very materially hasten the formation of sod. Early next Spring remove all the rough portion of the manure, but leave as much of the finer portion as possible on the grass. Do not cut the grass too frequently, nor very short during the heat of Summer. K.

Tools for Quack Grass.

I HAVE a considerable quantity of quack grass to contend with. It strikes me that somewhere in one of the back issues of THE R. N.-Y. you have mentioned an article or machine for gathering roots. Do you know of any such machine, and by whom is it manufactured? J. P. K.
Newfane, N. Y.

The two best implements we know of for getting out quack grass are the big cutaway harrow and the spring-tooth harrow. The first chops off the roots and tosses them to the surface. The spring-tooth drags them out and pulls them where they can be gathered. The Department of Agriculture at Washington issues a pamphlet on Johnson grass which will help all who are troubled by this sort of pest. In this pamphlet several forms of cultivators are described. They have slanting teeth or hooks in place of the ordinary teeth.

"DOESN'T that horrible noise your neighbor makes when he sharpens his lawn mower disturb you awfully in the morning?" "No. I go out and borrow it as soon as he gets it sharpened."—Cleveland Plain Dealer.

Growing Onion Sets.

WE have had good success in growing onion sets and for the benefit of R. G. C., page 852, and others who may be interested, we will give our experience. Land that will produce a good crop of ordinary onions, will grow a good crop of onion sets. The soil should not contain large quantities of raw nitrogenous matter. If stable manure is used as a fertilizer, it should be well rotted, and if possible, applied the Fall before planting. A liberal quantity of lime applied to the soil will show wonderful results. The Yellow Strasburg is a good variety, but we prefer the Yellow Globe Danvers. Almost all varieties do well, however. We sow the seed at the rate of from 50 to 60 pounds per acre. It is advisable to make the rows about 14 inches apart, running the seeder twice in the rows, as it is desirable to scatter the seed over as wide a space as possible in the rows. In order to have a good stand the seed should lay in the rows at the rate of at least 500 to the foot. The sets are usually kept clean with a handwheel hoe, unless they are grown on a large scale for commercial purposes, in which case the rows are made three feet apart so that a horse can be used in cultivation.

Onion sets are very sensitive to weeds and grass and for this reason the most dilligent care is necessary in cultivataion. In spite of all that can be done with weeding implements, there is always some hand weeding necessary, and the amount of this required will depend a great deal on the way the work of cultivating the crop is handled during the early part of the season. It should be the aim of the grower to secure a crop of very small bulbs as nearly uniform as possible. The ideal onion set is a round, plump little onion, the top being withered up to nothing. A bushel of the smallest sets will plant a greater area than the same quantity of the larger ones. Onion sets ripen in this section about the middle of August. Before harvesting we shear or cut the tops off with a scythe, and have found that a very good way to harvest them is by the use of a mason's trowel. After laying on the ground for a day or so we gather them and thinly spread them in a dry place. It is very important to dry and cure them thoroughly so that they will remain in an entirely dormant condition until wanted for planting. Storing them is often quite a hazardous matter, but we have had good success by storing in small baskets in a dry place, and also by freezing them as is often advised for wintering ordinary onions. If the latter method is used, care must be taken not to handle the sets while in a frozen, or even partly frozen condition.
Indiana. D. L.

A GALVESTON civil engineer was seeking support for a railroad in Honduras. During a conversation with one man, in attempting to put the necessity for a line clearly before him, the Texan asked: "How long does it take you to carry your goods to market by muleback?" "Two days." "Ah!" exclaimed the Texan "there's the point. With our road in operation you could take your goods to market and be back home in one day." "That is very well, senor," said the Honduran. "But what would we do with the other day?"—New York Evening Post.

When you write advertisers mention The Rural New-Yorker and you'll get a quick reply and a "square deal." See guarantee editorial page.

Let a Blaster Do That Job!

Ask us about an Atlas blaster who is ready to blow out stumps and boulders, blast ditches, and do other farm work for you with

Atlas Farm Powder
THE SAFEST EXPLOSIVE

He will do the job quickly and effectively, at about half the cost of hand or team work.

Valuable Farm Book Free

Our book, "Better Farming" tells how to grow bigger crops and improve the farm by using Atlas Farm Powder. Mail this coupon and get it free.

Atlas Farm Powder is sold by dealers near you.

Atlas Powder Company, Wilmington, Del.
Send me your illustrated book, "Better Farming." I may use Atlas Farm Powder

$10,000.00
Backs This Drill

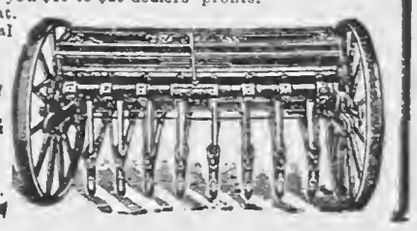
If this Hertzler & Zook Grain Drill does not satisfy you in every way, ship it back, and if we fail to return your money in full, paying freight both ways, we forfeit $10,000 which our bankers hold to protect you—you can't lose.

We make this big guarantee because we know this is the best drill on the market today—sows all kinds of grain, seed or fertilizer accurately and without waste. High, broad-tire wheels lighten draft. Extra large grain box. We also make a low down and plain seed drill. Sold direct from factory; saves you $10 to $20 dealers' profits.

Write for cat. alog and special offer.

30 Days' Free Trial

HERTZLER & ZOOK CO.
Box 120
Belleville, Pa.



The New GREENWOOD LIME and FERTILIZER DISTRIBUTER

TOP FEED—NO RUSTING—NO CLOGGING
Accurate indicator for 100 to 3,500 lbs. per acre, whether material be wet, dry, sticky, lumpy, heavy or light. Write for booklet R to
GREENWOOD MFG. CO., Lawrence, Mass.

CANVAS COVERS—wagons, hay stacks, machinery, porches. Roofing, waterproof duck, and heavy canvas for all purposes at wholesale prices. 10-oz. wagon covers 7½ x 12 feet. $3.60 prepaid. Write for prices, stating size required.
W. W. STANLEY, 50 CHURCH STREET, NEW YORK CITY

Hardwood Ashes Best Fertilizer in Use. GEORGE STEVENS, Peterborough, Ont.

More Rye

Rye serves the double purpose of a cover crop or a grain crop. In either case it pays to use the right kind of fertilizer on it—the kind that contains enough Potash to balance the phosphate. The mixtures we have told you to use on wheat are suitable for rye, but the

POTASH

may be even higher, since rye uses more Potash than wheat.

Use from 200 to 400 pounds per acre of a fertilizer containing 6 to 8 per cent. of potash.

If your dealer does not carry potash salts, write us for prices stating amount wanted, and ask for free book on *"Fall Fertilizers."* It will show you how to save money and increase profits in your fertilizer purchases. **Potash Pays.**

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York
HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 60 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

"THE FAVORITE HEN."

NO more entries for the hen contest can possibly be accepted. We already have nearly four times as many hens offered as we can utilize this year! We had no idea the suggestion would prove so popular. Within 10 days after the announcement we were fairly swamped with offers. Full particulars in the next magazine number of Woman and Home.

*

THERE has been some little mix-up regarding the Summer field meeting of the N. J. State Horticultural Society. It is to be held on the farm of John H. Barclay, at Cranbury on August 5 (Wednesday). It was first called for an earlier date but owing to a death in Mr. Barclay's family a change was made necessary. *Remember now that the meeting will be held on Wednesday, August 5.*

*

RUSSIA seems to be the great vetch country—where this crop has performed its greatest miracles as a soil improver. Large quantities of the seed sold in this country come from Russia. Thus far one great drawback to seed production here has been the difficulty in separating the vetch seed from rye or other grain grown with it. Now, we understand, a little separating device used in Russia is made in this country—giving good satisfaction. Such a machine will enable the farmers of a community to separate their own vetch seed and the result will be a great increase in this wonderful manurial crop.

*

WE judge that the meeting of the Connecticut Poultry Association at Storrs, on July 29-31, will be a storm center. The utility men and the fanciers are likely to have it out. We think the sparks will fly—and that is the chief mission of a spark. And by the way to do you notice how that "sour milk" pen of American Leghorns is crawling up on those English Wyandottes? They have steadily cut down the big lead of the English birds. We expect to see them win or come so close to it that there will be little margin. It is as interesting as a yacht race or a polo match and 50 times as useful. Good luck and many eggs to the American Leghorns.

*

REPORTS from France are that steam plowing is increasing quite rapidly in parts of that country. This will surprise many who have long been taught to understand that France is a nation of small farms on which hand labor is chiefly employed. It seems that even in France the labor problem and farm desertion are present and are changing the character of agriculture. In the old world thousands of boys and girls are bred to farming—through long generations of peasants. One would think such people would be "born farmers" and as such be fully content to remain on the farm. Yet it seems that even among this class the world-wide restless spirit is driving the best and more adventurous to the city. Thus French agriculture must change to a system which requires less hand labor. It would be impossible for the individual farmer to own a steam plow. Coöperative societies have been organized which buy these plows and rent them to the members. These societies combine and raise the money, buy the plowing outfit and charge a large enough rent to pay running expenses, a fair profit and a surplus large enough to pay for the plow in a few years. The charge for plowing six inches deep is about $3.50 per acre, while 10 inches or more deep costs $5.40. The fact that such rents will pay expenses, a profit and also pay for the plow is a mighty argument in farm coöperative work.

U. S. CONSUL WEDDELL reports from Athens a strange thing: "It is stated here that a committee representing a number of Greek families located at New York has addressed the Greek Ministry of Finance stating that they are prepared to return to their native land provided the Government will assist them and will also assign to each family a farming plot in Macedonia, say about 17 acres for each family. The settlers would be prepared to pay five per cent. of the purchase price of the land in advance and the balance in installments. It is believed that the Government is considering favorably the petition of the Greek committee."

These people came to this country in the hope of obtaining homes. Instead of getting out upon the land they were induced to remain in New York City where there is no possibility for them to secure land. Under the circumstances they will be better off to return to their own country. But what a singular outcome—going back to the old world to obtain land!

*

YOU see we stay right by this bumper wheat crop and its effect upon society. If we were living under a scientific combination of the golden rule and the law of supply and demand the bumper crop would jar the millenium a little nearer. The consumers would have cheaper bread while the producers would have far more money to spend for necessities or even luxuries. All this would start the wheels of trade and there would be a great business boom. The Hon. Bumper Crop would be elected unanimously as permanent president. That is a pleasant dream but the facts seem to be all against it. First, the price of wheat! Dean Jardine of the Kansas Agricultural College urges farmers to hold all the wheat they can away from the market:

> The present price, which is from 60 to 65 cents, is low, and is brought about largely because farmers are rushing their wheat to market faster than it can be taken care of, thus causing congestion at terminal points. The world's wheat crop is not unusually large, and there will be more wheat exported from the United States than in several years past, which is not likely to result in a low price for the coming year.

The price is expected to go even lower. Similar reports come to us from many wheat growing sections. On the reports of a "bumper crop" prices have fallen and the farmers who are obliged to sell are in many cases, receiving less for their crops than they did last year for fewer bushels of wheat. But, on the other hand what consumer has found his grocers' or bakers' bill any smaller because flour has fallen "in sympathy" with wheat? "Sympathy" in this case is good. It is like the quality of mercy which is strained to the breaking point. We repeat our statement that under present conditions of distribution and sale a "bumper crop" benefits every handler of the wheat except the farmer. We now see why the daily papers have been printing such wonderful crop stories. It was only a little of President Wilson's "psychological influence" to scare the farmers into dumping their grain upon the market.

*

A CERTAIN rich man, near New York, found that one of his boys wanted to become a farmer. So, very wisely, the young man was trained in practical farming. When it came to locating on the land the father expected to send the boy West, as that seemed to be the only land for large farming enterprises. Some friend took him to a section East of the Hudson river and pointed out the possibilities of the land for growing farm crops and the market possibilities as well. As a result a large tract of Eastern farmland was bought. It will be thrown together, smoothed, drained and organized—not as a gentleman's estate, but as a business-like farm. There is no question about the fact that for a man with capital the East today offers far better farm prospects than what we call the West. For example Rhode Island would not be called an agricultural State. Yet a man with capital and knowledge can go back from the railroads in that State and on 500 acres, more or less, make more clear profit at growing wheat, rye, corn, hay or any of the staple farm crops than he could in Kansas, Dakota or any of the so-called grain States. At growing potatoes, at dairying, fruit growing or other intensive crops, he can make far more than in the Western States, but we would let the Western farmers select the crops to suit them and then beat their record in the State of Rhode Island. In some of the deep level valleys of Vermont the difference would be still more striking. This does not mean that a man without capital or knowledge can take a small, unimproved place and make a fortune. Such a proposition is merely a dream. The East, however, has come to a time in its history where farmland offers good opportunities to the man with capital and practical knowledge. The strip of land 150 miles wide along the Atlantic is now, and will remain, headquarters for the best group of food buyers in the world.

*

VETCH growing for soil improvement is rapidly increasing on the thin, sandy soils of Western Michigan. This plant, when it can be made to grow, will solve the manurial problem in that section. It is often hard to get the vetch started on these thin soils but when once on the way it gives wonderful results. It seems as if each locality must develop its own plan of growing, and native or acclimated seed must be used. In a few localities machines for separating vetch from rye seed are being used and the seed crop is increasing. This is important because many of the failures with vetch are unquestionably the result of using the poor quality of foreign seed handled by most seedsmen. The outcome of the cover crop discussion seems to be for each section to find a particular crop which is best adapted to its condition. For example in some parts of the South nothing can be found superior to cow peas. In the upper South, Crimson clover gives superior results. North of Philadelphia those crops are uncertain and Soy beans, vetch, rape and turnips are better. On our own farm rye is the foundation of soil improvement. In Northern Vermont barley and rape are satisfactory. We cannot put down any sure "rule" for any man to follow. He must study out the truth for himself.

*

LAST year we had much to say about Mr. Shamel's work in California in finding the drone trees in orange and lemon orchards. The results showed a great difference in the producing power of trees growing side by side in the same orchard. These drone trees were worse than robber cows in a dairy herd in cutting down profit. It was proven that in the average grove a fair proportion of the trees do not pay for the labor and fertilizer spent on them. The same thing is more or less true of apple and peach orchards. Growers may deny it, but dairymen have denied that they fed robber cows when a test showed half of their animals were kept at a loss. But we can kill or sell the robber cow and buy another of better breeding. If the drone tree does not pay we can dig it out, but how can we make sure of a better one? Mr. Shamel claims that his work with citrus fruits has now gone far enough to show that bud selection from certain superior trees will enable us to cut the drone trees out. Most other scientists deny this and claim this is nonsense, but it must be said that each year brings new argument in favor of the theory. The Michigan Experiment Station has started some coöperative work in orchards in the State much like the work now being done in California. This will include apple and peach. There will be a careful test of each tree in the orchards for productiveness and buds for propagation will be taken from the best trees as well as from the drones. What we call a "drone" tree does not mean one which produces a poor crop because some natural soil defect or some disease affects it. We think a careful search will find trees naturally superior and naturally inferior and we feel confident that these naturally good or poor trees will carry much of this ability to produce through their buds.

BREVITIES.

HONEY production on the Bahama Islands is the latest scheme for organized farming.

AFTER a week of steady rain on the hay crop it becomes hard for us to believe some of these stories of drought.

KINDNESS means care. The milk of human kindness means cow's milk produced through the highest of human care and skill.

IF anyone tells you that the mulefoot hog is immune to cholera, tell him the mule has more sense than to believe fancy tales. The disease has killed many of this breed.

SOME people work for a public market, and then because it does not immediately change all trading conditions claim it is a failure. Stay by it and prove its value. You cannot hope to do it all at once.

PLEASE remember that sucking insects like plant lice cannot be killed by poisons. They do not eat like potato beetles or codling worms, but must be killed by some spray like oil or soap, which kills them by contact.

ANY Kansas farmer may have the name of his farm registered upon payment of one dollar to the county clerk. Farmers may then register a trade-mark name with the Federal Government, and this will protect the advertising of their products everywhere.

IT seems necessary to repeat again and again that the New York compensation law does not include liability for accidents in farm or household service. The laws in Connecticut and New Jersey *do* include these classes. Should a man live in New York, but conduct a farm in either of these other States, he would be liable to these State laws.

HOW CO-OPERATIVE BUYING IS DONE.

ON page 830 we printed a statement of the fertilizer business done by the Portage County organization in Ohio. This year these farmers distributed 20,000 tons at an estimated saving of $80,000. Whenever these figures are given they are severely criticized by manufacturers and dealers. We are repeatedly told that such trade would be impossible without a capital of $250,000 or $300,000. Where could farmers ever raise that or obtain credit for such an amount? Now THE R. N.-Y. does its best to obtain the truth for its readers, and it will not knowingly print any false or misleading statement. Is it true that these Ohio farmers are buying fertilizer in this way? If so, how are they able to do it? We have obtained the facts, fertilizer contracts and documents, which show that farmers are actually buying the goods. As to the way it is done, the following clear and concise statement ought to satisfy anyone:

The plan adopted is very simple and workable. In brief it is as follows: Men are selected who will handle the business at each shipping point in the organized territory. Farmers are requested to hand their order to these chosen agents. Each order is accompanied by a $2 advance payment as a guarantee of good faith. The agent forwards the orders to the company, and goods are shipped to the agent. Terms are simply sight draft attached to the bill of lading. This the agent must pay before the goods are delivered to him. Thus the company has the money to its credit before the farmers receive the goods. The farmers are pledged to pay cash so that the agent is out the use of his money not longer than 36 hours. For this and his time and trouble he is allowed a commission of 75 cents per ton. The only capital therefore necessary to swing the deal is money enough in the pocket of the farmer to pay for the goods he has ordered.

Thus far, we understand, the farmers have raised the cash and paid it when the goods arrived. The system is not a new one. It has been operated on Long Island, in New Jersey and elsewhere with some modification. The farmer's saving comes through a *large combined order direct*, and prompt cash payment. Another saving is made through the farmers' knowing just what their soil needs and buying chemicals to meet its requirements instead of guessing at it. The system is also a good thing, or can be made so, for the manufacturer who can make contracts with responsible people knows what his trade will be and receives prompt cash payments. At least, it seems to be true that manufacturers are competing for this trade.

New York State News.

AMENIA FIELD DAY.—The fifth annual field day at Amenia will occur on Saturday, August 15. The Amenia Field Day Association is now an incorporated society, and an effort will be made to have this the largest and best outing that the society has ever had. Men of national prominence will be secured as speakers, but their names are not yet announced. Besides making it a field day of the ordinary sort there will be an exhibit of farm produce and farm implements of a purely local nature. In this matter the Dutchess County Farm Bureau management will co-operate. The moving picture concerns have already made application to take pictures of the events.

STATE FAIR EXPENSES.—A policy of retrenchment in expenses has been adopted by the State Fair Commission whereby expenses in all departments will be limited to 15 per cent. of the amount expended last year. The situation was created by the fact that the Legislature appropriated only $30,000 for premiums instead of the $63,000 asked for by the Commission, and made no provision for maintenance of the grounds, an item in itself of $20,000. In adopting a retrenchment policy it is said that the members of the Commission were actuated to a certain extent by the fact that if appropriations exceeded and a deficit resulted they would be personally liable. But were this the case there is no doubt but that they would have been reimbursed by the next Legislature. It was decided, however, not to reduce the premium list from the $63,000 figure, as an opinion of the Attorney-General had been secured which was to the effect that the revenue from gate receipts could be used to make up any deficiency in the premium moneys. He bases his opinion on the statement in the supply bill which says: "For deficiency in appropriation for premiums for fair of 1914, $30,000." This, he says, would seem to contemplate an appropriation for a deficiency, and intimates the reception of funds from other sources available for the purpose. The Attorney-General also expresses the opinion that the commissioners would be personally liable to exhibitors should they become entitled to premiums under the advertisements of the Commission in that regard, should they exceed in expenses the amount appropriated by the Legislature and the net receipts available.

MONSTER GRANGE PICNIC.—It is planned by the State Fair Commission to have a monster Grange picnic one day at the State Fair this Fall. It will be held on Grange Day, and as we understand it, the Commission has offered reduced gate admissions on that day which should appeal to all members of the order who can attend. The plans are not yet announced but will be soon. In the large hickory grove on the fair grounds tables will be provided for Grange parties. It is said that two Granges in Yates County have already announced that they would guarantee an attendance of 500 from their jurisdiction.

COMPENSATION INSURANCE PREMIUMS.—It is announced that the workmen's compensation premiums amounted, up to July 6, to about $15,000,000 which has been paid into the State by manufacturers. This amount will be largely increased by the latter part of the week, as Friday is the time limit for the issuance of policies to manufacturers. These are the premiums paid for State policies, and of course there are many others in other companies. One concern filed its intention of carrying its own insurance, and also filed bonds amounting to $18,000.

STATE GRANGE SCHOLARSHIPS.—The following persons have been awarded scholarships of $50 each by the State Grange Scholarships Committee, for the short course at the State Agricultural College: George Ohlem, Ashville; Nellie Brainard, Ellington; Myron K. Morse, Halcott Center; Rollin Case, Frewsburg; William Stockham, Holley; Frank K. York, Smithville; R. M. Giles, Skaneateles; L. P. Poole, Manorville; Ray Thomas, East Bloomfield; E. R. Hall, Camillus; Earl McNulty, Java Center; Edith Brainard, Ellington. These awards have just been announced by the committee, consisting of W. H. Vary, W. N. Giles and George Warren.

OTHER GRANGE ITEMS.—Grange activities in Sullivan County are especially noteworthy this Summer. Last month a Pomona or county Grange was organized at Liberty, by State Secretary Giles, with D. H. Clements as master. A subordinate Grange was organized at Hortonville, the same county, on June 23, by County Deputy David Muirhead. A masters' and lecturers' association was also organized at Liberty on June 29.——A new Grange was organized at Brewster, Putnam County, on June 18.——The Depauville Grange dedicated its new hall on July 4, State Master Vary officiating.——There are now over 850 subordinate Granges in the State. Of this number there are 23 having a membership of more than 500 each, and four that exceed 600 each. The largest Grange in the State is Webster Grange with 725 members.

J. W. D.

Canadian Crops and Trade.

The Ottawa authorities report a great increase in export of Canadian wheat to South Africa. Total Canadian trade for the fiscal year exceeded $1,000,000,000, an increase of $26,697,554 over the previous year. Wheat and barley are making good progress. The area under Spring wheat is reported to be 10,230,500 acres—185,500 acres more than last year. The area of Fall wheat expected to be harvested is 924,300 acres—3,300 acres more than in 1913. The acreage of oats is placed at 10,811,000 acres, compared with 10,434,000 acres last year, an increase of 477,000 acres.

Wheat Shortage in France.

In a fairly favorable season France produces nearly enough wheat for home use. This year the crop is so poor that imports of 50,000,000 bushels or more are anticipated. The import records of previous unfavorable years, extending back 15 years, are: 52,000,000 bushels, 1897-98; 73,000,000 in 1910-11; 45,000,000 in 1913-14. The harvest of 1908-09 was large enough to bar imports. The past four years have all been short, though less than 10,000,000 bushels in some cases. North Africa has been one of the large sources of supply for France, the remainder coming from Australia, Central Europe and the United States. Our sales to France last year were about 4,700,000 bushels.

Potatoes from Maine.

THE U. S. Department of Agriculture has adopted new quarantine regulations for shipment of Maine potatoes. This is to prevent the spread of powdery scab. The new rules go into effect August 1. The regulations provide that no potatoes shall be moved from any quarantined area unless they are duly certified as fit for either table or seed use and are packed in accordance with certain specified rules. To obtain the necessary certificates for shipments, growers must apply for inspection by a Federal inspector, and all potatoes intended for seed use must be stored and handled according to certain prescribed methods. Lots in which any of the potatoes are found to be infected with powdery scab or any similar disease will not be certified under any circumstances for seed use. They may, however, be certified for table use after the diseased potatoes are removed and destroyed.

Delaware Conditions.

THE long drought was broken in the lower half of this county on June 27, when we had a heavy rain, which greatly benefited all growing crops. The upper part, however, is still dry, and crops suffering badly for rain. Wheat harvest is over, but thrashing is being delayed by light showers, which keeps the straw damp. Scarcely any wheat is stacked here, all being thrashed from the field. The dry weather cut the strawberry crop short, as it also did the pea crop for the canneries. Some growers did not realize enough from their pea crops to pay for the seed and fertilizer. Early apples are being picked and marketed in large quantities, and good prices are being realized for them. Some have received as high as $1.30 per bushel for their early Transparent apples. Pastures which were getting short have rapidly revived in the section where we had rain. Harvesting hay has just commenced. There is scarcely more than a half crop. The early white potato crop, which has suffered greatly by the drought, will soon be ready to dig. Eugene Shallcross, who has a 16-acre potato patch, purchased a pump with a capacity of 125 gallons per minute, and a four horsepower gasoline engine and is irrigating his potatoes. The experiment is being watched with much interest by his neighbors.

Dover, Del. C. H.

Government Crop Report.

IN the Winter wheat sections harvesting conditions have been favorable. Thrashing is under way except in parts of Kansas, where it is delayed by rain. In the Spring wheat States weather has been ideal for growth of the plant. The Western corn-growing States have had abundant rains, but the Ohio Valley and southward is suffering for rain. Drought continues serious in Texas, where the late cotton is being pinched. The Atlantic States have had good rains from Virginia northward. Apples promise a large yield in Michigan, Maryland, Colorado and North Carolina. West Virginia will have a large peach crop; Maryland and Delaware light.

The latest estimates of the Bureau of Statistics put the Winter wheat yield at 655,000,000 bushels, 32,000,000 more than last year; and Spring, 275,000,000, against 230,000,000. Winter wheat is yielding three bushels per acre more than the average.

The corn prediction is 2,868,000,000, or 421,012,000 ahead of last year; oats, 1,201,000,000, or 81,000,000 ahead of 1913.

Percentage conditions of immature crops July 1 were: Spring wheat, 92.1; corn, 85.8; oats, 84.5; barley, 92.6; rye, 92.9; hay, 80.8, or .3 more than last year; apples, 64.2, or 5.8 ahead of 1913. The planting of white potatoes is 3,708,000 acres, 140,000 more than last year; present condition, 83.6, which is 5.1 under the 10-year average; estimated yield, 356,000,000 bushels, or 24,000,000 in excess of 1913; sweet potatoes, acreage, 593,000, or 32,000 under 1913; condition 77.1 per cent., 9.4 under.

Co-operative Apple Selling in Nova Scotia.

I SEND some of the figures of the United Fruit Companies of Nova Scotia, Ltd., which now includes 39 companies working under special acts of the Nova Scotian local House of Parliament and pooling their apples of the same grades.

Total apples handled last year 274,000 barrels; potatoes, 38,700 barrels; apples graded, 79,531 No. 1, 36,459 No. 2, 158,000 No. 3. There were 170 different varieties.

The price was, including absolutely everything, $2.57 per barrel for No. 1, No. 2 and No. 3, but of course this was not the way the money was divided. Total expenses for the Central (not including the local packing), management, etc., of the different companies, $12,300 for apple and potato accounts, and $5,452.48 for supplies (expenses for purchasing): General manager, $2,500; secretary, $1,200; organizer and inspector, $1,200; European representative, $1,111.50; Halifax representative, $1,000; office salaries, $1,847.03. Total salaries, $8,858.53, and travelling expenses of $1,963.63.

In addition to this, other expenses—printing, etc., came to $3,831.32, or a cost of handling the apples and potatoes of four cents a barrel. This year, with twice the crop, the cost should be less than that, even.

JOHN BUCHANAN.

Farm Product Prices.

The Bureau of Statistics gives the following:

AVERAGES FOR THE UNITED STATES OF PRICES PAID TO PRODUCERS OF FARM PRODUCTS.

Products.	May 15, 1914.	May 15, 1913.	May 15, 1912.
Hogs, per 100 lbs.....	$7.60	$7.45	$6.79
Beef cattle, 100 lbs.....	6.33	6.01	5.36
Veal calves, 100 lbs.....	7.59	7.17	6.23
Sheep, 100 lbs.	4.87	4.91	4.74
Lambs, 100 lbs.....	6.49	6.66	6.16
Milch cows, per head.....	59.85	54.80	45.63
Horses, per head.....	139.00	145.00	144.00
Honey comb, per lb.....	.137	.138	.137
Apples, per bushel.....	1.46	.94	1.29
Peanuts, per lb.	.051	.047	.049
Beans (dry), per bu.....	2.31	2.18	2.52
Sweet potatoes, per bu....	.93	.93	1.19
Cabbages, per 100 lbs.....	2.05	1.58	2.98
Onions, per bushel.....	1.53	.87	1.77
Wool, unwashed, lb.....	.172	.163	.178
Clover seed, per bushel....	7.87	10.74	12.53

Alfalfa seed, per bu....	8.38	9.75	....

Woman and the Home

From Day to Day

It Couldn't Be Done.

Somebody said that it couldn't be done,
But he with a chuckle replied
That "maybe it couldn't," but he would be one
Who wouldn't say so till he'd tried.
So he buckled right in, with a trace of a grin
On his face. If he worried he hid it.
He started to sing as he tackled the thing
That couldn't be done—and he did it.

Somebody scoffed: "Oh, you'll never do that—
At least, no one ever has done it";
But he took off his coat, and he took off his hat,
And the first thing we knew he'd begun it.
With a lift of his chin and a bit of a grin,
Without any doubting or quiddit,
He started to sing as he tackled the thing
That couldn't be done—and he did it.

There are thousands who'll tell you it cannot be done,
There are thousands who prophesy failure;
There are thousands to point out to you, one by one,
The dangers that wait to assail you.
But just buckle in with a bit of a grin,
Then take off your coat and go to it.
Just start in to sing as you tackle the thing
That "cannot be done"—and you'll do it.

—Edgar A. Guest in Brockton School Helper.

*

AMONG household conveniences in wire is a dish drainer that has a compartment in the center in which flat silver is stood upright to drain. It costs 40 cents. Another convenience is a wire vegetable basket, to be used when draining vegetables after boiling; it comes in different sizes, at 12 and 18 cents. A wire lettuce washer or salad basket costs 40 cents.

*

REGULAR wear soils a light-colored raincoat as much as any other garment, but it should never be cleaned with naptha, chloroform, gasoline, or similar cleansing agents, because they injure the rubber in waterproof materials. Lay the garment flat and scrub it on both sides with abundant soap and water. Rinse with clear water, wipe off, and hang it up to dry. Of course wringing must not be attempted.

*

THE Philadelphia Record says that one afternoon a very stout woman was rambling along a country road when she suddenly noticed a little boy walking closely beside her. Not knowing the youngster, she was naturally somewhat surprised.

"Look here, little boy," she heatedly cried, "why are you following me along like that? Go away from me instantly."

"I ain't doin' nothin', lady," pleaded the little fellow. "Please don't send me away."

"You must go away at once," repeated the perplexed woman. "Why do you wish to follow me?"

"Because," was the startling rejoinder of the youngster, "you are the only shady spot along the whole road."

*

THE New York Child Labor Committee has been investigating the cases of children working in the tenements in this city. One case reported was a girl 14 years old, who made artificial violets. She had to make 576 of these flowers, and paste them into wreaths to earn 10 cents. Her average weekly earnings were under $2. Another family of flower makers consisted of a grandmother and three girls, aged eight, 13 and 15. These three children, working with their grandmother, were able to earn between $6 and $7 a week. They began as early as five in the morning, worked till school time, then began work again after school, continuing until late at night. Many children working in the tenements are five to eight years old, and the Child Labor Commission is anxious to do away with this class of labor entirely.

*

THE statement was once made by a famous general that an army is no stronger than its feet, and those who are forced to keep about, while suffering discomfort in those useful members, will appreciate this saying. A housekeeper who must be much on her feet, will find it worth while to remember this. Ill-fitting shoes, and especially old ones with worn soles and crooked heels, lead to endless troubles. The idea that "anything is good enough" for wear around the house is a sad mistake. Proper bathing and rubbing relieve foot troubles, and a careful rubbing down of calluses with manicure sandpaper often prevents troublesome corns. Frequent change of stockings is another help. Sea salt, baking soda and borax are all helpful to tired or aching feet. Often, after a long and busy morning's work, a woman who has no time for actual rest will find her fatigue wonderfully lessened if she can take a foot-bath and change shoes and stockings.

Seen in New York Shops.

THE dealers in lace and embroidery are complaining bitterly of dull trade, due to changes in fashion. Irish lace is quite out of style here, though it is said that Queen Mary's visit to Paris has induced its use there. A great deal of the finest underwear is now made up as lingerie sans garniture, entirely without lace, or is trimmed with Madeira work, directly on the fabric, instead of edgings and insertions. A great many of the most fashionable blouses have no lace or embroidery, also wash dresses. The disappearance of masses of coarse machine-made lace and embroidery certainly shows a refinement of public taste, and we should like it to continue. Manufacturers tell us that there is a great improvement in these machine-made trimmings, many of the better grade being "hand-finished," so that they resemble more closely the "real" laces.

Parasols take many strange shapes this year, some being veritable domes, while others have the spread of a Chinese pagoda; another style is very flat and shallow. The standard style is a moderate-sized rather flat coaching parasol. This is especially pretty in changeable taffeta; the more elaborate ones have shaped, not gathered circular flounces, forming a point at the tip of each rib. More showy are parasols covered with Roman stripes or checks; the latter are often black and white check with a deep satin border of some bright color. Velvet parasols are seen in some shops, very handsome and costly ones, but they seem absurdly incongruous. A striking feature in many new parasols is the length of the handle, 52 inches, which accommodates stick-up hat trimming.

A pretty little touch is given to the white vestee worn with a colored linen gown by sewing on the pearl buttons with a crow-foot of colored silk. Four-hole buttons are used; first the stitches are put across diagonally, then from each side to one hole already used. It is very simple, but gives the effect of a decorated center to the button.

Millinery foliage this year seems to take every color unknown to nature. Even where the flowers copy nature closely, the leaves are often some odd color, such as bronze, light brown, or blue gray. Leaves shading from pale yellow to deep orange were seen on one hat. With the vogue for white hats came pure white foliage; laurel sprays and wreaths, and bunches of "dusty miller," some of these creations resembling quite strongly the decorations of a wedding cake. White chip hats are very often trimmed with flowers or foliage entirely white. A very odd trimming on a sailor hat was a wreath of white leaves at the base of the crown, above this a wreath of yellow roses, and rising above the roses a ruche of orange tulle. A leghorn hat had a wreath of bright orange leaves with a bunch of brown roses at the back, while another had a wreath of yellow leaves and an oddly shaped bow of cobalt blue velvet. Hats of white rice straw are trimmed with pink foliage and roses, while oddest of all was pink roses with Canton blue leaves trimming a white hat. Wreaths of brown foliage are often combined with tiny flowers in bright shades of yellow, blue or pink.

Little handkerchiefs of very sheer linen had a picot edge crocheted over the narrow hem in colored thread, and a little design in colored cross-stitch in the corner. All the work was fairy-like in fineness.

White pique bedspreads printed in colored flowers vary in price from $1.50 up. The handsomer ones, ranging in price from $2 to $5.50, are block-printed in the old-fashioned way. They have borders and center designs of fruit and flowers in bright colors. These bedspreads are offered especially for Summer use in country homes.

Berry Puddings.

Blackberry Pudding.—Wash and drain large plump berries. Butter a drop cake tin or old deep cups and put in berries till half full. Cover with sugar and add a dot of butter about half as large as a small walnut. Cover with the batter given below and bake forty minutes in a moderate oven. Serve with sweetened cream.

Batter.—Beat together two eggs, two small cups of flour, pinch of salt and enough sweet milk to make a batter a trifle thicker than pancake dough. Lastly add two small teaspoons of baking powder. Nearly fill the cups with this mixture and bake.

Huckleberry Pudding.—Wash and drain the berries and place in a pudding dish to the depth of one and one half inch. Sprinkle lightly with flour and add one level tablespoon of butter cut in little bits. Make your batter by beating together two eggs, one cup of sugar, one and one half cups of flour, one and one-half teaspoons of baking powder and sweet milk to make rather a thick batter—not quite so thick as cake dough. Pour over the berries and bake in a steady oven. Over the top when half done put several pieces of butter. Serve with cream.

Mulberry Pudding.—Take two cups of mulberries and one cup of stoned cherries, as the mulberries are rather flat alone. Put in a baking dish and cover with a batter as for blackberry pudding. Omit the butter. Serve with whipped cream.

Red Raspberry Pudding.—Make a biscuit dough by any reliable recipe and roll it rather thin. Put half in the bottom of a buttered baking dish and cover with a one inch layer of crushed red raspberries sweetened to taste. Bake the other half of the dough in another pan and when done place on top of the berry layer. Cut and serve with cream. This is a "mussy" looking pudding, but very good.

Berry Tapioca.—Soak and cook the tapioca allowing as much tapioca as berries. Sweeten to taste and beat well to distribute the sugar. Have ready individual dishes half filled with strawberries, red raspberries or blackberries drained as dry as possible. Cover with the warm tapioca and serve warm or cold with or without whipped cream.

Old-Fashioned Berry Blanc Mange.—Make the blanc mange by any tested recipe and pour into individual cups to harden. Drop cake tins will answer or the little individual fancy tins most housekeepers have. Turn out on little fancy plates and add to each serving two tablespoons of crushed and sweetened berries. Red raspberries are perhaps the best for this with a dash of currant juice to impart a slightly tart flavor.

HILDA RICHMOND.

A Suggestion on Contentment.

WE read many articles in agricultural publications on two subjects, how to interest and keep the boys and girls on the farm, and life in our country towns. What is written on either of these subjects has a tendency to destroy the influence of the other until we are led to feel as Edward Everett Hale says, there has been so much said, and it has been so well said, that it is hardly necessary to say anything more. Yet there is one point that should be emphasized in capital letters, i.e., that we shall never succeed in interesting young people in the farm home, or teach them to love and respect their native town, its people, schools, churches, or public officers by running these things down. No, it is about time, if we would have the coming generation respect and love their surroundings to begin to boom them a little. Older people were never known to interest young people in things, in which they took no interest themselves. This is generally the reason why the boys leave the farm and why many girls often long to when they don't. As the little girl told her mother, they realize that "women have a hard time of it anyway." The older people often seem more discontented and grumble at the farm, and farm life more than the younger ones.

Young people should be taught to love their native town, and its people in their childhood. With some, this love is instinctive; while with others a continued course of grumbling on the part of their elders against everything and everybody in the township, has a strong tendency to alienate their affections, and make them long for new scenes and people of a more interesting mold. They eventually find that the world is the same the world over with the exception of climates, etc. And I will admit that our New England climate has its "drawbacks" but it has compensations as well. "Laugh and the world laughs with you," is as true of country as city. If we love our home and native town we are apt to be interested in it. Enthusiastic parents invariably have enthusiastic children. Unless you take an interest in bettering the conditions of farm life or town affairs you are hardly in a position to grumble at those conditions.

And often those conditions are not as bad as we try to make them appear. Many farmers of today engaged in the struggle for wealth are in the same condition as other people of different professions engaged in the same pursuit. They are unhappy not so much because they have no means of enjoyment, as because they cannot afford to take time to enjoy themselves. There is no place in the world where the environment is more suited to promote happiness than on the farm. Here you may have without an effort, the birds and flowers, green grass and beautiful trees, beautiful landscapes and sunset skies; and if you would command more pleasures, you may easily obtain them, if you will not make the childish mistake of wishing for all things on the land and sea at one and the same time.

Children who have too many pleasures are generally the most discontented, and this is sometimes the case with children of older growth. We must not live only for pleasure, though while doing our duties we may find it. In studying the great text book of nature country people may find not only profit but unlimited pleasure; unlimited because there is always something new to learn. There is no end to this volume and we need never throw it aside. There are no graduates in the study of botany, geology, ornithology, etc. They may be indefinitely pursued, always with interest. These are the pleasures which have been "added unto" the joys of farm life, and are very effective in interesting the boys and girls on the farm where they have been intelligently introduced. ALICE E. PINNEY.

Keeping a Stove Clean.

Will some of THE R. N.-Y. family tell me how to keep the kitchen stove clean where one room has to do duty for two, dining room and kitchen? We have always had two rooms, and I have washed my stove all over, so as to have *clean* pots and pans, and yet prefer a clean washed stove. But since moving here I must put my large cook-stove in the dining room, as the little kitchen is too small. I have the stove polished, but cannot scour the bottoms of the pots and pans every meal, so now I am disgusted with kitchen stove polished. This stove has been washed for 10 years, ever since we have had it, and was always clean if not so good looking. The lids were always red, as there is a continual fire in the stove whenever the weather permits. I thought you might know of a varnish or something that could be used, and would not smell so badly. MRS. W. H. G.

We should like to hear from others as to this problem. Personally, we have never approved of this plan of washing the stove. If it were a galvanized surface it would be different, but it is not; cast iron is not intended for water treatment, and oxidation must result. If the stove is well brushed we do not think that the cooking utensils are badly soiled, unless soft coal or wood is burned, and the soot resulting would soil kettles whether the stove was washed or polished. After 10 years of washing it will be difficult to give the stove a hard polish and we think part of the trouble comes from this, and there will be improvement if the stove takes a better polish. What do other housekeepers say to this problem? Have they tested any varnish that is desirable for a kitchen stove?

The Rural Patterns.

When ordering patterns always give number of patterns and measurements desired. Price of each pattern 10 cents.

8213, Girl's dress. Cut in sizes 10, 12 and 14 years. Size 12 years requires 4¼ yards of 36-inch material with 4½ yards of banding. 8158, Girl's dress. Cut in sizes 6 to 10 years. Size 8 requires 2½ yards of 36-inch material for dress and 1¼ yards any width for bloomers. 8257, Girl's costume. Cut in sizes 10, 12 and

14 years. Size 12 years requires 3¾ yards of 36-inch material with ⅜ yard 27 inches wide for trimming. 8044, Child's undershirt. Cut in sizes 1, 2 and 4 years. Size 2 years requires 1⅛ yards of 36-inch material. 8214, Child's petticoat. Cut in sizes 2, 4 and 6 years. Size 4 years requires 1½ yards of 36-inch material.

7555, Ladies' house jacket with peplum. Cut in sizes 34 to 42 bust measure. Size 38 requires 2⅜ yards of 36-inch material. 8103, Ladies' dressing jacket. Cut in sizes 34 to 44 bust measure. Size 38 requires 2¾ yards 36-inch material. 7896, Ladies' house gown. Cut

in sizes 34 to 44 bust measure. Size 38 requires 6 yards of 36-inch material with ½ yard 18 inches for collar and cuffs. 7626, Fancy work aprons. Cut in one size. No. 3 requires ⅞ yard of 36-inch material. 8118, Misses' aprons. Cut in sizes 14, 16 and 18 years. Size 16 requires 3¼ yards of 36-inch material with short sleeves.

MORALLY speaking, disaster and triumph are impostors. The cheers of the moment are not what a man ought to think about, but the verdict of his conscience and the consciences of mankind. —Woodrow Wilson.

Hot Weather Desserts.

FROZEN COFFEE.—Prepare a thick sugar syrup by boiling together a quart of water and two large cupfuls of sugar for fifteen minutes. Skim the syrup carefully, add a large cupful of the strongest black coffee and a tablespoonful of gelatine that has been softened in a little cold water. Cool and strain when the gelatine is dissolved, stir in the stiffly whipped whites of two eggs, and freeze to the consistency of soft snow. Serve in thin, tall glasses, each portion capped with a tablespoonful of sweetened whipped cream.

Raspberry Ice.—Make a syrup of four cupfuls of water and one and two-thirds cupfuls of sugar; boil for 15 minutes. Cool. Add two cupfuls of juice, strained from mashed raspberries through a cheese cloth, and two tablespoonfuls of lemon juice. Freeze.

Maple parfait.—Beat four eggs slightly; pour on slowly one cupful of hot maple syrup. Cook in double boiler, stirring constantly, until mixture coats the spoon. Cool. Add one pint of thick cream beaten until stiff. Mold; pack in ice and salt and let stand three hours.

Frozen Biscuit.—One pint of sweet cream, 24 macaroons, two-thirds of a cupful of pulverized sugar; whip the cream to its utmost consistency, then pulverize and add the macaroons, then the sugar and a scant teaspoonful of vanilla. Pack in a tin pail that has been rinsed with cold water, cover tight and pack in ice and salt. It will be ready to use in five or six hours, and will be found delicious.

Lemon Ginger Sherbet.—Wipe eight lemons thoroughly with a clean, soft cloth and from two of them shave off the very thin yellow peel which contains the flavoring oil, but be careful that you do not get any of the white, bitter part of the rind. Then cut all the lemons in half and press out the juice, strain it. Put four cups of granulated sugar in a saucepan with two quarts of boiling water and boil until clear, skimming off the scum as it forms; then add the lemon juice and strain all through a piece of cheesecloth. Beat the white of an egg until light and foamy, but not stiff, and pour the strained syrup over this; mix well and turn into a freezer; turn until the mixture is stiff; then stir in quarter of a pound of candied ginger sliced thin and let stand a little while before serving.

Peanut Brittie Cream.—Make a quart of vanilla cream by the usual rule. When this is half frozen take out the dasher and add a half pound of peanut brittle or two or three bars of peanut candy put through the meat-chopper; the result is a light brown cream tasting like caramel, with the nuts all through it; it may be served in glasses or put in a brick.

A Miner's Safe.

EVERY year we are asked for methods of keeping food without ice, during hot weather. The following advice was given us some time ago by a reader in Arizona:

The miner's safe has a light wood frame about four feet square and four feet high, running to a peak at the center of the top about six feet from the base. This frame stood on four legs about one and one-half or two feet above the ground. It was finished completely with wire fly-screen, had a shelf and a door. The whole thing was then covered with burlap. It stood in a shed at the rear of the shack and the ground underneath sloped gently toward the canyon below. At the top of the peak was a hose from which water dripped constantly onto the safe, and was absorbed by the burlap. The evaporation kept meat and other articles cool in the warmest weather and the extra water drained away. The water was piped from the mine above. These safes are used a great deal in the West by large contractors who have large numbers of men at work far away from cities and shipping points and who have to board their help.

There is also used a great deal in Southern California, a safe known as a "cool closet" or cupboard. It is the same as any other small cupboard, built in the house, but has no floor nor top. These are made of wire fly-screen. It has movable shelves of screen. The air circulates in through the cellar and out through the top through ventilators set in the floor or walls for the purpose. Each apartment in the large apartment houses of Los Angeles has its own cooling closet. Of course the screen shelves are stayed with slots and are movable. The door to this closet is solid.

Country Picnics.

COUNTRY picnics when held at the home of some one of a neighborhood usually mean a prodigious amount of work to be done by the receiving family, first in borrowing from the neighbors, dishes, plates, knives, forks, spoons, etc.; next in more or less cooking and in waiting on the assembled guests; and lastly the washing up of dishes and returning them to their respective owners. Let me tell you the way we do in our suburban neighborhood.

So far as the eating is concerned, the word is passed that a meeting will be held at neighbor Brown's, Jones' or Robinson's, as the case may be, and at the appointed time will be seen the members of the different families wending their way toward the designated home—each family bearing its usual supply of eatables for such an occasion, which have been previously cooked and prepared in each individual home, and also for every person—who expects to partake of the good things—is carried from each respective time home a generous-sized flat tin pan—usually a 12 to 14-inch milkpan—with knife, fork, spoon, and tea or coffee cup, and a plate may be added if wished. When the repast is served, all eatables are set on tables, pies and cake properly cut, etc., and each visitor with individual pan forms into line around the table and helps himself or herself to the viands, placing same in the pan and then carrying it to the place chosen for eating. Generally during Summer months we quickly arrange ourselves in groups on the grass under the trees, etc.

Hot coffee, lemonade or other suitable drinks are usually supplied by the host. After the eating each family gathers up their respective lot of pans and dishes and carries them away, as they are, washing them at home. In this way the work as well as the play becomes a community affair and no one family is burdened with a lot of hard work in order that the neighbors may have a good time. Just try it and you will very soon "get the habit." J. B. BARLOW.

DAISY FLY KILLER placed anywhere, attracts and kills all flies. Neat, clean, ornamental, convenient, cheap. Lasts all season. Made of metal, can't spill or tip over; will not soil or injure anything. Guaranteed effective. Sold by dealers, or 6 sent by express prepaid for $1.

HAROLD SOMERS, 150 DeKalb Ave., Brooklyn, N. Y.

TYPEWRITERS ALL MAKES
Prices $15.00 up. SOLD or RENTED anywhere at ¼ to ½ MANUFACTURERS' PRICES, allowing RENTAL TO APPLY ON PRICE. Free Trial. Installment payments if desired. Write for catalog 15
TYPEWRITER EMPORIUM, 34-36 W. Lake St., Chicago

CIDER PRESSES
The Original Mt. Gilead Hydraulic Press produces more cider from less apples than any other and is a BIG MONEY MAKER. Sizes 10 to 400 barrels daily. Also cider evaporators, apple-butter cookers, vinegar generators, filters, etc. Fully guaranteed. Write for catalog.

HYDRAULIC PRESS MFG. CO.
137 Lincoln Ave., Mt. Gilead, Ohio.
Or Room 119 L 39 Cortlandt St., New York, N. Y.

CIDER MAKING
Can be made profitable if the right kind of machinery is used. WE MAKE THE RIGHT KIND.
Send for catalogue. Established 1872.
BOOMER & BOSCHERT PRESS CO.
312 West Water Street, Syracuse, N. Y.

MAKE BIG PAY DRILLING WATER WELLS

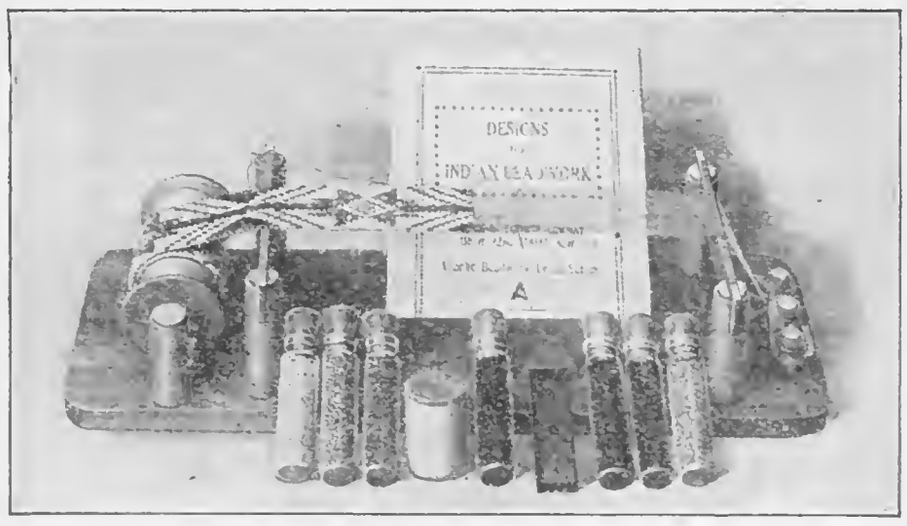
Our Free Drillers' Book with catalog of Keystone Drills tells how. Many sizes; traction and portable. Easy terms. These machines make good anywhere.
KEYSTONE WATER DRILL CO
Beaver Falls, Pa.

JOB PRINTING—250 each of envelopes and letter heads $2. Samples.
Ryder Print Shop, Barnerville, N. Y.

WELL DRILLING MACHINES
Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock. Mounted on wheels or on sills. With engines or horse powers. Strong, simple and durable. Any mechanic can operate them easily. Send for catalog.
WILLIAMS BROS., Ithaca, N. Y.

HANDY BINDER
JUST the thing for preserving files of THE RURAL NEW-YORKER. Durable and cheap. Sent postpaid for 25 cents.
The RURAL NEW-YORKER
333 West 30th Street, New York City

Indian Bead Work



NOTHING is more fascinating or more in vogue at this time than **Indian Bead Work articles.** We have procured an outfit for making these articles, which will be sent, delivery charges prepaid, for

ONE NEW YEARLY SUBSCRIPTION
OR
THREE YEARLY RENEWAL SUBSCRIPTIONS
(One of these may be the renewal of your own subscription for one year.)

This outfit consists of a Patented Loom for making articles, an instruction and design book, a spool of cotton, twelve H. Milward Sons' needles, seven bottles of colored beads—dark blue, green, light blue, black, red, yellow and white—a complete outfit to start the work.

Every woman knows and appreciates the value of these home-made articles.

Your neighbor needs *The Rural New-Yorker.* If he is not a reader get his subscription. If he is a subscriber get his renewal.

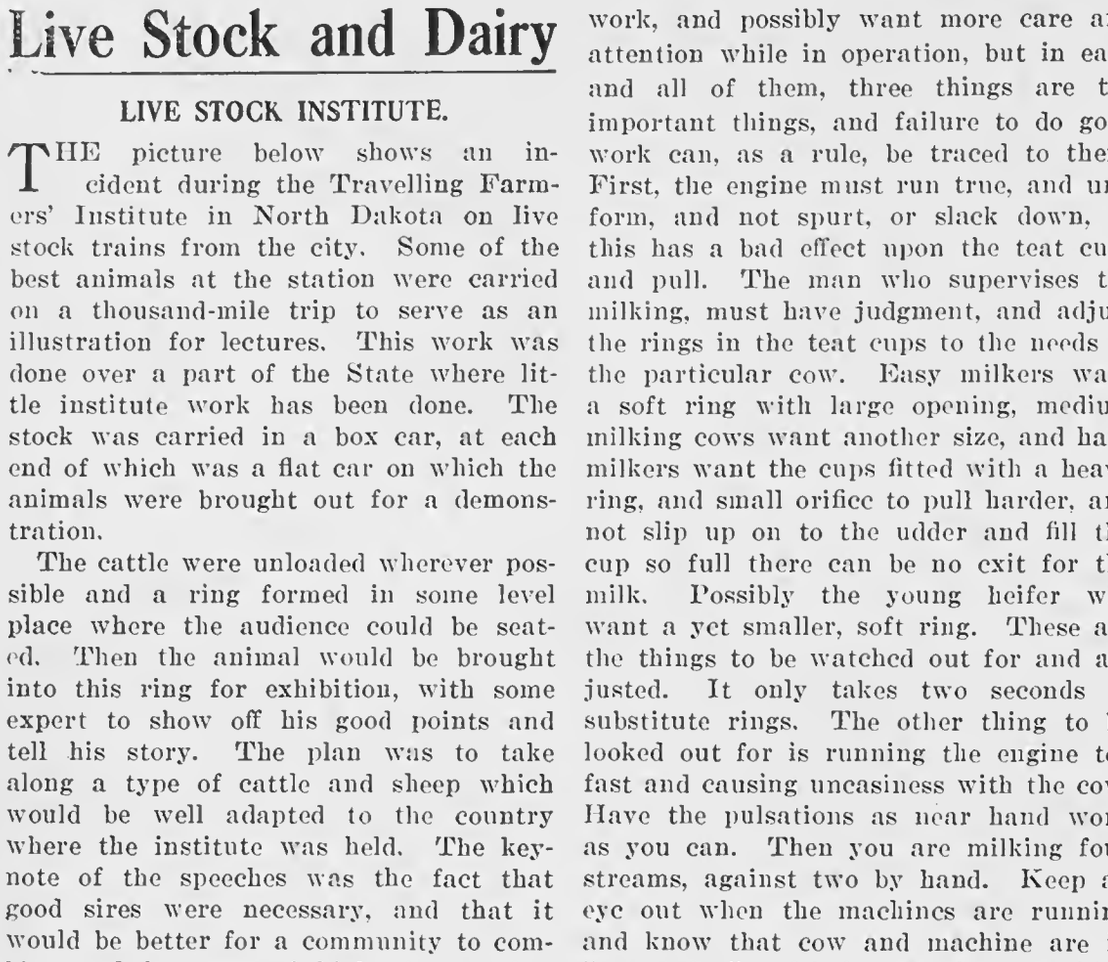
THE RURAL NEW-YORKER, 333 W. 30th St., NEW YORK CITY

Live Stock and Dairy

LIVE STOCK INSTITUTE.

THE picture below shows an incident during the Travelling Farmers' Institute in North Dakota on live stock trains from the city. Some of the best animals at the station were carried on a thousand-mile trip to serve as an illustration for lectures. This work was done over a part of the State where little institute work has been done. The stock was carried in a box car, at each end of which was a flat car on which the animals were brought out for a demonstration.

The cattle were unloaded wherever possible and a ring formed in some level place where the audience could be seated. Then the animal would be brought into this ring for exhibition, with some expert to show off his good points and tell his story. The plan was to take along a type of cattle and sheep which would be well adapted to the country where the institute was held. The keynote of the speeches was the fact that good sires were necessary, and that it would be better for a community to combine and buy one of high class rather than take the same amount of money and



BEEF CATTLE AT A DAKOTA R. R. INSTITUTE.

purchase three or four of inferior breeding. The interest in pure live stock throughout North Dakota is growing constantly. After a long period of growing wheat and flax a Dakota farmer needs some form of live-stock husbandry for the sake of the soil: For a long time it was claimed that corn could not be successfully grown in North Dakota. Now varieties have been worked out which will ripen during the short season and hardy strains of Alfalfa can also be grown in the State. Thus with corn and Alfalfa, the live stock business becomes promising and the station is doing good work in carrying these facts up and out to the farmers.

THAT MILKING MACHINE.

I HAVE little new to add to a former article on page 418. The machines are still milking as in the past, and something like 1,000 new machines were set up in Northern Ohio during March. The sales indicate that many dairymen are seeking the once supposed impossible and now finding it not so impossible as it then appeared. For the last week I have been interviewing by 'phone and word o' mouth, the farmers who are using these machines daily, and my first question is "What are the weak points in the milking machine you use?" and the gist of the replies is, "The man who runs the machine." This must be taken into consideration, whatever kind or make of machine used. While not complicated, they are of necessity of fine adjustment, and the machine must be kept in order, its parts working smoothly. Men have all sorts of luck running farm machinery. Some men cannot run a farm wagon successfully. A milking machine will not go to the lot, get the cows, start itself, and do the operation of milking without some supervision and knowing that everything is working smoothly.

Some machines have many more parts than others, a different plan of doing the work, and possibly want more care and attention while in operation, but in each and all of them, three things are the important things, and failure to do good work can, as a rule, be traced to them. First, the engine must run true, and uniform, and not spurt, or slack down, as this has a bad effect upon the teat cups and pull. The man who supervises the milking, must have judgment, and adjust the rings in the teat cups to the needs of the particular cow. Easy milkers want a soft ring with large opening, medium milking cows want another size, and hard milkers want the cups fitted with a heavy ring, and small orifice to pull harder, and not slip up on to the udder and fill the cup so full there can be no exit for the milk. Possibly the young heifer will want a yet smaller, soft ring. These are the things to be watched out for and adjusted. It only takes two seconds to substitute rings. The other thing to be looked out for is running the engine too fast and causing uneasiness with the cow. Have the pulsations as near hand work as you can. Then you are milking four streams, against two by hand. Keep an eye out when the machines are running and know that cow and machine are in "sympathy," and before you let a machine loose, feel of the udder and see if it is slack, and if not, handle it a little and let the machine pull a half moment longer. I find that some men after milking go down the line with a pail and see if all the cows are clean milked, and now and then find a cow with a litle milk, possibly a pint, still back. Other men rely wholly upon the feeling of the udder when removing the cups. Now and then a cow will not give down, and hand milking does not always get it at that time. One cow in a hundred, possibly, will not become reconciled to the machine and has to be hand milked.

"You have to look sharp all the time," I said to a milker. "Yes, why shouldn't I? This four-milker is milking against six men. It pays me to look sharp. It is saving me money." This man was milking 36 cows alone, night and morning, and Neighbor Kent's two boys are milking over 50 cows.

Are these machine-milked cows holding out in milk yield? I was told by a strange dairyman that they were milking up to the freshening period, when all cows are dried, fully as well as they did in hand milking days and the yearly yields are as great. It is better to milk a heifer with the machine before the calf ever sucks. The machine then is her calf from the start. There is a belief that cows are better started in when fresh rather than farther along in lactation.

Are the machines short-lived? Not if taken care of, and kept in adjustment. There is very little wear. That all comes of cup rings, and pump packing and where vacuum pails and the like are used, see that the packing does not leak air. Otherwise a machine should last for years, whatever the make of machine. Do the cows break in easy to milk? As a rule yes. A cow always hand milked at the front may be disturbed some at the start to have the machine attached from the other side as must be when two machines are run in company. A kicker as a rule submits at once without protest or kick to the operation of the milker. JOHN GOULD.

The Law About Milk Cans.

I ENCLOSE letter from a Mr. Walsh, and was this morning served with summons made returnable in 20 days in Supreme Court of Kings County, N. Y. I do not understand just what the charge is, but believe that Walsh visits milk producers, and, if foreign cans are found, serves notice that they are liable to a fine. I understand that he gets his living from the fines or fees. What is the law about this? READER.
New York.

Section 270 to 274 of the General Business Law of New York provides that no person shall, without the consent of owner, shipper or his agent, use, sell, dispose of or traffic in any milk can which has the name or initial of the owner stamped, marked or fastened on it. If one does use, etc., any such can, it is presumptive evidence that its use is unlawful. The can may be taken posession of by the owner or his agent wherever found, and a violation subjects the offender to a forfeit of $50 for every violation. The action may be brought in the name of any agent without joining the owner of the cans.

These provisions appear to give the owner of marked bottles authority to follow the bottles and bring action in a county where the owner lives, which may be far from the place where the bottles are found.

The intent of the law is to prevent milk cans, which are expensive property, being diverted from their owners. There are a number of inspectors to look after this work. Mr. Walsh being one, and at least part of their pay comes from the fines collected. Possession with consent of previous owner is lawful, so any man who buys, trades or has milk cans bearing another man's initials given him should be sure to get written consent of the previous owner specifying the identical cans. This protects him against suit or annoyance.

Strong Butter.

WILL you give me information about separator butter? It gets strong within two weeks. G. M.
Williamson, N. Y.

There are several things which might cause butter to become strong or rancid. In the first place, the milk must be kept as clean and free from bacteria as possible until it goes into the separator. There is considerable probability, especially in warm weather, that the milk pails may carry bacteria. Utensils containing milk need more than an ordinary amount of scrubbing in order to keep them clean. Milk will dry into the seams and rough places unless the greatest care is used to prevent it, and it is sure to cause trouble. Thorough scalding of all milk utensils is advisable, but a good scouring powder, with plenty of elbow grease is most esential. The same is true of the separator. All separators have plenty of places for milk to collect, and in some separators there are lots of places hard to get at. The cream should be cooled immediately after separation, and not mixed with older cream until cold.

After churning it is necessary to wash the buttermilk from the butter quite completely or the buttermilk will soon develop objectionable flavors. In warm weather the butter is apt to "come soft," and then it is difficult to remove the buttermilk completely. Churning should be at a sufficiently low temperature so that the butter will come in shot-like granules, and when in this condition should be thoroughly washed with cold water. Then, of course, the butter should be kept in a place where it cannot absorb strong odors from outside. C. L. M.

Fly Blankets for Cows.

I AM informed that enterprising dairymen put fly blankets on their cows during the day while on pasture to spare them the annoyance of flies. Is this done from a humanitarian standpoint for the comfort of the cows, or from the standpoint of increased product?
Flemington, N. J. M. N. G.

Mostly because the cows do better when thus protected. Some dairymen do consider comfort first, but most of them are after more milk, and they find that the protected cow does better. This plan is sometimes tried with calves and young stock, and it pays.

NISCO
"The TROUBLE-PROOF SPREADER"
is the choice of the business farmer who values spreader perfection. It positively will do more and better work in less time than any other machine. It took us 15 years to perfect this mechanical masterpiece which we know to be
100% EFFICIENT
Thoroughly pulverizes the manure, spreads it wider and more evenly than any other spreader. Easy to load, since sides are only 41 inches above ground. Bed is from 3 to 5 inches deeper than any other so-called "low down" spreader. Built for thorough work and lasting service.
FREE Circular in Colors and Descriptive Catalog
Gives reasons why "Nisco" and "New Idea" are the "Best Spreaders on Wheels." Shows why our machines are practically trouble-proof. Settle the spreader question for all times by writing us Today.
New Idea Spreader Co., Box 17 Coldwater, O.

Cow-Ease
Prevents Ticks.

KEEPS FLIES OFF
Cattle and Horses
and allows cows to feed in peace, making More Milk and More Money for you. A clean, harmless liquid preparation, applied with a sprayer. Keeps cows in good condition, and saves five times its cost in extra milk.
TRIAL OFFER
If your dealer cannot supply you, send us his name and $1.25, and we will deliver prepaid to your address a half-gallon can of COW-EASE and SPRAYER for applying. For West of Missouri River and for Canada, above Trial Offer, $1.50.

Satisfaction or Money Back.

NEW FADS IN BREEDING.

HERE is something many of us are doing year after year, and we think we are on the right track. One dairyman in the Western Reserve in Ohio says that a number of his neighbors bred up good grade Holsteins for eight or 10 years. Their herds were good milk producers, did a little better than 3 per cent., but now those farmers are after the bonus offered for high-testing milk, and have turned in Jersey bulls in their herds. This breeder has been preaching to his farmer friends the idea of sticking to their breed and securing a purebred bull from high-testing ancestry. He tells his neighbors that they are going to be right back where they were a decade ago, when they try breeding an inferior grade Jersey bull, a yearling, on a large Holstein grade cow. He says, "When you feel like trying this out, just drive until you find the man who has, or look through your farm papers stacked away in the garret for years back, and you will get good, sensible advice against the idea. "I tried it," he remarked, "and seven chances out of 10 the inferior abilities of both breeds predominated, the small volume of the Jersey and the light test of the grade Holstein. I did have one which gave a creditable mess for a Holstein and tested 5 per cent. Don't try to break against the engine under high speed, or you are going to skid, which is true in breeding."

W. J.

CERTIFIED MILK PRODUCERS.

THE annual meeting of the Certified Milk Producers of America, held at the Copley Plaza Hotel, in Boston, June 25 and 26, was not the success it should have been, due to several causes, not the least of which was lack of knowledge of the affair by the people of Boston who are interested in improving the city's supply and improving conditions generally. Why the meeting was held in Boston, if not to boost the business here, I do not know. Certainly to have all these members from all over the country come to Boston instead of meeting in some other city in the centre of the country, which would be handier to reach than Boston, is something I do not understand. Boston is not a certified milk city, comparatively speaking, as I believe only about one per cent. of Boston's supply is in this class, although I believe much milk very near this class, and believed by many to be just as safe and good in every way, is sold here, produced by a system along the same lines, but perhaps not santioned or guaranteed by a medical association or commission as certified milk must be. At the same time thoroughly competent men, many of them doctors, chemical experts or bacteriologists, keep a careful oversight of the production of the same, and certainly the product is high-class, safe milk. Other producers also use a careful system of sanitation, test the cows—in fact, keep only tested cows—and have other arrangements according, and receive high prices for their product; yet they are not in the certified class, and perhaps do not care to be. It is claimed, and probably true, that Boston has as good and safe a milk supply as any other large city, and plenty of high-class milk to supply all who demand such and are willing to pay the price.

The various addresses were very good, and were along the right lines, but as no Boston people were there to hear them, or Massachusetts producers, either, for that matter, it looked to me as if the effort was wasted—certainly to a large extent—on instructing the public to use this class of milk and inducing a larger production and demand for same. The importance of closer relations between the certified milk producers and the medical milk commissions, and necessity of uniform standards, methods and requirements was thoroughly discussed, first by Dr. Pearson, of Iowa, and later by the members, and much difference of opinion was brought out. All believed this was very important, but how to bring it about was a hard question. The producers seemed to believe they should have equal voice in these matters, or if anything, the more important part in moulding these requirements, etc.

S. L. Stewart, of Newburgh, N. Y., gave the following advice to produce milk low in bacteria: First dry grooming, washing by disinfectant of flanks and other parts of cow, rest half hour, wash udder with germicide, then wash again with pure water, dry with towel, spray barn with clean water to lay dust. Wash and sterilize hands before milking, handle and strain each cow's milk separate, and use clean cheesecloth for each pail of milk. Take samples directly after straining through cloth. Send milk to milkroom by trolley. Then men wash after milking each cow. Only 50 to 60 bacteria per cubic centimeter should result by following along these lines.

A. E. P.

N. E. MILK CONDITION.

A MOVEMENT started and pushed by the Boston Chamber of Commerce through its agricultural committee, assisted by the U. S. Department of Agriculture, the departments of the several New England States, and the State Granges of the same, is on foot to investigate the production of milk for Boston market, the transportation of milk, the handling of milk and the consumption of milk for the same; to find if possible a remedy which will improve conditions along the line, and put this important industry back where it belongs at the head of all industries and on a paying basis for the milk producers of this market and in such shape that it will be a paying proposition for dairy farms now idle to restock and reproduce the needed supply of fresh milk and other dairy products and also beef cattle for the needs of our market. As one of the speakers at the meeting said if the shoe industry of New England were in such shape as the milk business appears to be, a howl would be heard that would awake the Nation. We must wake up to the importance of this milk industry as above even the shoe industry and if we cannot have this in shape to be proud of in 10 years' time we should be ashamed of ourselves and our State.

The plan sketched by the Chamber and accepted by the conference is to have hearings in each State by the Agricultural and Grange heads, gather all facts possible and work out a remedy to improve conditions all along the line; to find out as nearly as possible the exact cost of producing, hauling and handling milk—in short to go into all phases of the business thoroughly. Some of the facts brought out at this meeting will help open people's eyes and others will necessarily follow.

One of the U. S. Department men who has been working on dairy conditions in New England lately offered the following: A section containing 266 farms was examined and the following results of profit were obtained, that is the owner's profit after expenses were deducted. On 118 of these farms dairying was conducted and average profit to owner was $256 per year. On 40 of them poultry was the feature and $479 resulted as owner's profit. On nine which conducted a fruit business $1,150 profit to the owner resulted. On 99 farms where general farming was carried on $300 was the profit resulting. Dairying stands at the bottom of the list. I have stated the above as profits to the owner, it was rather the earnings and perhaps not all profit.

Another fact brought out was Connecticut is the only State of the six having as many cows today as five years ago. The average production per cow in New Hampshire is 6,000 pounds; cost of production 4 9/10 cents per quart. The average profit on a 4,800 in New Hampshire is $16.44. Vermont is the largest producing State of the six. This State produces more butter than all the rest and also has a larger percentage of milk producers than any of the others. Also has large percentage of dairies testing 60 per cent. Too many low producing cows are kept, it is true, but these can not be eliminated at this time as not nearly enough 8,000-pound cows are available to supply the milk for this market and the 4,000-pound cow must be used until a supply of the former can be raised to supply our demands.

We believe the proper authorities are taking these matters up, that is, the ones who will get results if profitable results to all interested parties can be got. The Chamber in accepting and placing the dairy business of New England on an equally important basis as the shoe business and other large industries of New England is a step ahead. It is putting an important industry where it belongs and good must come from this placing. At the same time farmers and producers must not expect all important results unless they take hold themselves and do things. In order to do a thing well do it yourself, applies in this case and we must take advantage of the help offered us in this case and do a lot ourselves. Our first duty is to organize and work together and with the help now offered and with conditions ripe to push forward and reap a reward and regain much of the lost ground. We are going to accept this help in the spirit it is offered and do our share in this good work. I am sure we have a secretary who is working hard for us. Let us back him to the limit and we can come into our own.

A. E. P.

DAIRYING IN MADISON CO., N. Y.

THE dairy conditions in this part of the country have changed greatly in the last few years, the old cheese factories, where butter and cream cheese were manufactured, are a thing of the past hardly any being left in our county. The milk shipping stations and Jew product factory, where butter and cream cheese quently the New York City health inspectors have visited us and their inspections and scorings have caused a great deal of dissatisfaction, especially among the better classes of dairymen. Many farms on which large dairies were formerly kept have only milch cows enough to supply the family. The high prices of dairy cattle have taken hundreds of cows from this part of the country in the last three years, the past year being the record breaker in shipping them out to other States. Our pastures are very lightly stocked and the feed is abundant and likely to continue so. Many of our farms have been sold to Western people and they are not practical dairymen like the men brought up on the dairy farms of the East and do not understand the science of making bossy pour out the milk. Regarding the price and the marketing of milk and its products I am not posted, but hear a great deal of complaint about the high prices of feed and the low price of milk. The kinds of cows kept in this section generally are grade Holsteins. Our farmers have been using mostly purebred sires for many years. Madison County has produced some of the best purebred Holstein cattle of the times and they have been shipped into many other States. We now have a Holstein breeders' association with sale stables at Earlville, Madison County, where annual and semi-annual sales will be held. We also have other sales in the county.

F. D. H.

New York.

FLY SPRAYING PAYS.—A farmer in Michigan said he leaned over his meadow fence and watched one of the liveliest races he ever saw between his yearly bull and one of his oldest cows. They chased round and round the field, and he figured on getting off easy that night when it came to milk that cow. He said it was nothing but flies which was worrying the stock, and the remainder of his herd were thrashing through underbrush in self-defense on the opposite side of the field. "Well," he said, "I know a lot of the good dairymen spray with fly dope, but I thought it wouldn't pay on my scrubs to give them a spraying each morning; but I tried it out, and it does pay. It only takes a few minutes to do the work, and the cattle are comfortable all day, and even at night when they are brought to the barn for milking I find there is little or no trouble arising from their fighting flies while I milk. I believe, although I have not reduced the observation to figures, that the cows give more than enough to pay for the spray and the time used in applying it. Besides, they are kept in better condition."

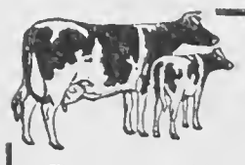
JUSTAMERE FARM, Middletown Springs, Vt.



Purebred Registered

HOLSTEIN CATTLE

Do you consider dairy farming a real business, a man's job or simply a side issue? Are you keeping high-producing Holsteins or just cows?

A good Holstein is little short of a perpetual motion milk-making machine, that while in milk uses her food for milk production and when dry stores up body fat to be converted into milk fat as soon as she freshens. She will earn 50 per cent. on the cost of her feed.

Why not keep this kind?

The Henyard.

"Swat the Rooster."

THIS was the advice disseminated all over the State of Missouri by the State Poultry Experiment Station and June 6 was set as the proper date to perform the act. Director Quisenberry of the Station reports that practically all of the buyers and wholesale dealers in eggs and poultry coöperated with the Station in this work, with the result that the estimated number of roosters killed in that week in the State of Missouri was over a quarter of a million. These 250,000 male birds killed by the farmers on "Rooster Day" mean an immense saving to the farmers of that State who produce eggs for market. Practically all the hatching for the season is now finished, and the male birds consume food and serve no useful purpose. But the saving of the food they would consume is a comparatively small matter; the great saving is in the condition of eggs that reach the eastern markets. It is estimated by various authorities that this saving for the State of Missouri alone will be from one million to three million dollars. In eggs that have been fertilized by the male bird it is almost impossible under ordinary conditions to keep the chick germ from developing more or less in hot weather. Later this germ dies, and we have the "rots and spots" so often referred to in the New York market.

Director Quisenberry states that he has some eggs on his desk that are over a year old. They have never decayed; simply dried up, by evaporation through the shell. What an immense saving would be made if every State that produced poultry would follow the example of Missouri. There is another feature worth considering too; the farmer who has had no male birds all Summer and Winter will be more likely to buy well-bred males of some good laying strain in the Spring, and thus increase the laying capacity of his flock, and also avoid the ills of inbreeding.

The report of the egg-laying contest in Missouri for the month of May shows 20,418 eggs laid, an average of about 20 eggs for each hen in the contest. The purebred hens in this contest, coming from all parts of the world, have averaged in six months about 15 eggs more than the ordinary farm hens lay in a year. The highest pen average has been made by the English White Leghorns, 133 eggs per hen, in six months. The English pen also broke the record for May by laying exactly the number they did in April, viz., 257. Three hens laid every day in May, 31 eggs in 31 days. They are No. 2 of Barron's White Leghorns; No. 592 of B. F. W. Thorpe's Barred Rocks, and No. 1009 of the Linfield Poultry Farm, New Zealand. This was a White Leghorn. The pen records of the different countries is as follows:

S. C. White Leghorns, best English record, 1,330 eggs; S. C. Reds, best American record, 1,152 eggs; S. C. Reds, best Missouri record, 1,152 eggs; S. C. White Leghorns, best Vancouver Island record, 980 eggs; White Wyandottes, best Ontario, Canada, record, 949 eggs; S. C. White Leghorns, best New Zealand record, 942 eggs; S. C. White Leghorns, best British Columbia record, 904 eggs; S. C. White Leghorns, best Australian record, 844 eggs; S. C. White Leghorns, best South African record, 797 eggs.

In the contest just closed in New Zealand the best pen of six pullets averaged 278 eggs each. They do not trap-nest; they give the pen record only.

GEO. A. COSGROVE.

Enlarging Henhouse.

I HAVE hatched out about 600 White Leghorns in incubators, ages range from 10 days to eight weeks; 450 of these I have in a house 10x30 feet with shed roof seven feet high front, five feet back, one square foot muslin and one square foot glass for each 10 square feet floor space. These 450 are four to eight weeks old and have open hopper before them containing a commercial scratch food and a dry mash consisting of 50 pounds bran, 50 pounds wheat middlings, 50 pounds cornmeal, 25 pounds meat scrap. They also have sour milk before them at all times. All are on large free range, and from appearances I shall have at least 400 pullets to keep for layers this Fall and Winter. How much floor space shall I require for this number, the increase to be added right on the present house and to be of the same relative dimensions? Are my muslin and glass proportions correct? Should the house when completed be partitioned, or can I safely house 400 or 450 together? Is my feeding method correct or what improvements would you suggest up to the time they attain their growth? They seem to thrive excellently on it, the larger ones crowing at seven weeks and weighing about one pound. Hatches averaged only 60% but losses only 7½% to date. What are the feeding values of the curds and whey in sour milk? I notice that the chicks will gorge themselves with the curd parts if the whey is strained off but being ignorant of its relative feeding values I have kept it stirred up but they would consume double the amount if strained. This is my first experience in chickens and I have practically taken all my information from your columns. I wish to endorse the sour milk (lactic acid) theory for white diarrhœa. I was of course compelled to purchase all my eggs, and one lot of 100 were badly infected, but having read the symptoms I immediately recognized it and filled the little chicks up twice daily with sour milk, using an eye dropper. Of 58 hatched I lost 17, but did not start treatment until they were four days old. Another lot of 124 I lost but one and they are now four weeks old, but these I treated immediately on removal from incubator and twice daily until they began to eat lots of it themselves. I have no doubt, however, that if treated as advised in a recent issue of THE R. N.-Y. losses could be reduced to a minimum. C. B. H.

Pattersonville, N. Y.

Your results in artificial hatching and rearing have been excellent, and there is nothing to criticise in your methods of feeding. The same mash moistened with skim-milk and fed once or twice daily, in addition to keeping it, dry, before them would hasten the development of the chicks if that seemed advisable; they will do well, however, on the dry mash alone. A flock of my own being fed in the same way are doing splendidly, though a smaller flock that is getting milk moistened mash twice daily is outstripping them. It is a question, though, whether the more rapid development is of any particular advantage, except in the case of late hatched chicks. Whey has about one half the feeding value of whole skimmed milk, containing most of the carbohydrates but practically none of the protein and fat. Where the supply is at all limited, I should feed whey and curds together. Chicks on free range with a pan of sour milk and an open hopper of dry mash constantly before them will eat a surprising amount of the latter.

Your new house may be in one compartment or divided, as you prefer. There is no reason why 500 fowls may not well run together if they have room enough, from three to four square feet of floor space per fowl. I would not build 10 feet deep; sixteen to twenty is better in every way and more economical. The more nearly square a building of given floor space, the less material required for the walls. A deep house with open front, with or without muslin curtains, is superior to a narrow one, and cheaper to build. Your results while feeding sour milk would seem to confirm the growing favorable impression of its value. M. B. D.

Poor Egg Yield.

WE have about 50 chickens, Plymouth Rock, and only get about five to seven eggs each day. They are from a good laying strain and did well for a while. We feed them all they can eat, but to no effect. L. W. H.

Iowa.

Without knowing anything about the methods of care and feeding used, it is difficult to suggest any reasons for the poor performance of a flock. They may be fed all that they will eat and yet not have a suitable ration for egg production. Their food should consist of mixed whole grains, not corn alone, and a mash of mixed ground grains, fed either wet or dry; to which should be added some animal product like meat meal, beef scrap, cut bone or skim milk. The large breeds, particularly, should be made to exercise, either by feeding their grain in deep litter or by being given free range; they should also have crushed oyster shells and grit, as well as fresh water, always before them. Some care needs to be taken that they be not overfed and allowed to become excessively fat and sluggish. M. B. D.

Early Moulting.

I HAVE about 800 Leghorn layers in one of the Corning type of houses. My hens have laid heavily all of the season, giving a 70% yield for several weeks. Just now and within the past 15 days they have fallen off to less than a 50% yield. I have 40 setters or over, shut up and a number do not keep to the nest permanently, but go clucking around. Also, and here is where I wish information, perhaps as many as 150 of the hens are molting. Is not this too early, or is it as it should be? Is it a good or bad thing? What effect will it have upon the Fall laying? C. E. S.

Pennsylvania.

Observations at the Cornell Agricultural Experiment Station have convinced the authorities there that the early molting fowls should be discarded as unprofitable, it being an indication of lack of sustained laying power. Such hens are apt to lay a few eggs during the natural reproductive season and then go into molt with a cessation of production. My advice would be to cull these out and dispose of them lest their sleek appearance in the Fall when the really good layers and late molters are ragged should lead to their retention as breeders. M. B. D.

White Diarrhœa.

IS there any remedy for white diarrhœa? I keep losing hens with it.

Maine. A. R. BODGE.

Questions of this kind are almost impossible to answer, without seeing the dead chickens, examining the ovaries and knowing something about the plant. I have never had any experience with old hens dying from this disease, but have been told by one of our State experts that hens do at times die of white diarrhœa. The only suggestion I can make is for Mr. Bodge to send to Storrs Agricultural Experiment Station, Storrs, Conn., for Bulletin No. 77, in which there is a very fine cut of an infected and normal ovary; cut open and examine the ovaries of a few dead hens, or send a few ovaries to some experiment station for a bacteriological examination; then he will know if he has white diarrhœa or some other trouble. As you know, there is no cure for hens that are affected at present.

EDWARD S. PARSONS.

A Lice Powder.

HEREWITH I enclose a sample package of "Absana," represented as the best possible "lice powder" on poultry; the price being 25 cents for 2½ pounds. M.

This material appears, from an examination, to be much the same thing as the Cornell lice powder. Here is the formula for making that powder, which costs about five cents a pound:

One-fourth pint of crude carbolic acid, mixed with three-fourths pint gasoline is thoroughly stirred into 2½ pounds plaster of paris. The whole is forced through a sieve to break up the lumps. It is then allowed to dry in the air and when dry is tightly bottled. The stock mixture remains effective indefinitely. To apply this powder, make nail holes in the top of a tin can and use the can as a shaker. The fowl should be held by the legs with its head down.

Chicks Poisoned by Salt.

HAVING recently lost a number of chickens from eating a mixture of corn starch and salt used for making beads, I would like to know if there is anything that can be done to save them, if the like should happen again. The first died in three hours after eating the mixture, and some lived two days and then died. Most of them died within 12 hours after eating. H. S. J.

Ohio.

In this, as in the case of having eaten any poisonous material, the proper remedy would be to administer a quickly acting cathartic to flush the deleterious matter from the intestines. Two teaspoonfuls of castor oil, given as soon as it became known that a considerable quantity of salt had been eaten, would probably be as efficient as anything. When sufficient poison of any kind has been absorbed from the digestive tract to cause death a cathartic would, of course, do no good, but given sufficiently early, it will save many cases. M. B. D.

A Louse Exterminator.

NOT long ago I received the circular of a "louse exterminator" for which great things are claimed. The price is $2.25 per pound. It has the appearance, to me, of being nothing more than the ordinary blue ointment or mercurial ointment, with a little red coloring matter to disguise it. They claim in their circular that one application of this the size of a pea, applied to the part directly below the vent will rid the bird of lice and keep them entirely free for six months. Last Summer I procured a 33⅓ per cent. solution of mercurial ointment and mixed it half and half with vaseline and applied it to some very lousy hens, and up to date they are entirely free from lice. I also applied it to my pullets before sending them to the contest, and while at Storrs sometime ago, looked my birds over and found them entirely free from body lice.

I have no doubt the claims are correct and that the salve sent out at $2.25 per pound will do what is claimed for it. However, I buy the blue ointment in five-pound lots at 50 cents per pound, and mix a pound of it with a pound of vaseline at 10 cents per pound, making two pounds cost 60 cents or one pound 30 cents. All of the vermin in the poultry business are not on the poultry; some of them are on the poultrymen, and while blue ointment is an admirable eradicator of vermin from the hen, THE R. N.-Y. is equally as good an eradicator of the vermin from the poultrymen.

FRED'K M. PEASLEY.

Chicks Eating Droppings.

DO you know of anything to stop chicks from eating their droppings? The chicks are S. C. White Leghorns, two months old, and are fed growing mash and beef scrap mixed together with oil meal and bone meal; have plenty of green food thrown to them, also grit; sour milk twice a week and fresh water at all times. W. S. Y.

New York.

With plenty of litter on the floor of the brooders I have never known chicks to eat enough of their droppings to cause any trouble, though they will pick at them, more or less. I can only suggest that you use plenty of litter and give the chicks as much outdoor range as possible. Close confinement conduces to vicious habits of all kinds, many of which could be avoided if the chicks were given more liberty. M. B. D.

The Henyard.

THE EGG-LAYING CONTEST.

JULY 3 ends the thirty-fifth week of the contest. Egg production holds up well, 3,143 eggs having been laid during the week, which is only two eggs less than the previous week.

A new high score was made this week, the English White Leghorns laying 63 eggs. The record is 6-7-7-6-6-6-5-7-6-6 and one egg laid on the floor. These birds did not do very well on the start, and I had a number of letters inquiring, "What is the matter with Barron's Leghorns this year." I wrote Mr. Barron about it, and his reply was, "Those birds are bred right, and they will come along all right." I was much impressed with his confidence in the ultimate results of his breeding; and the way they have been "coming along" lately shows that the confidence was warranted.

One of the "experimental pens" from Storrs Agricultural Station takes second place with a score of 56. Glenview Poultry Farm is third with a record of 53, and Branford Farm fourth with a score of 52. All the above are White Leghorns. Three pens laid 51 each, and five pens laid 50.

The week's record follows:

Pinioning Fowls.

WOULD you give directions for performing the operation of pinioning on fowls? I understand that it is done when the quill feathers come out on the wings, but don't know how to do it. T. J. W.

Washington.

The best way to pinion fowls is to pluck the primaries or flight feathers from one wing. These are the much stronger feathers which grow from the first joint of the wing. When these are plucked and the secondaries left intact, the bird shows no unnatural condition. The same results are obtained by using a heavy pair of shears and clipping these flight feathers two or three inches from their base. In the Winter time the feathers should be clipped. In the Summer time they may be pulled. By removing these feathers from only one wing, the bird, in trying to fly, only succeeds in going sideways and is unable to steer itself or fly to any extent. A. L. C.

A Custom-hatcher's Troubles.

NO HARD AND FAST RULES.—The writer has for a number of years done a limited business in custom hatching each Spring and pleads guilty to having been a poultry crank for many years. I have tried over and over to lay down certain rules of procedure in hatching, etc., only to have the next batch of eggs upset all rules and theories. Exactly similar treatment of eggs has produced great variations in results. One odd thing I have noted is that as yet I have been unable to get a successful hatch of White Plymouth Rock eggs though I have tried repeatedly from different breeding pens and in different years. This Spring I made four trials. The first 50 eggs produced 16 chicks, every egg fertile; the second 50 gave 24, all eggs fertile but two; the next two fifties were from the same pens, set just one week later, and 58 eggs tested infertile. I immediately took up the matter with the man who brought the eggs and he declared no change had been made in the pens as to feed or mating, there being two males in the pen at all times. Can some one explain this radical drop in fertility in one week? I got 24 strong chicks from the remainder of the eggs. With all other breeds I have had uniformly good hatches, though Leghorn eggs always seem to come through in larger numbers. Many incubator manufacturers tell you to keep machine tightly closed till hatch is over. Repeated experiments with my machines convince me that I get more chicks if the dry chicks are kept removed. In case it is necessary to keep cover off any length of time a light sprinkling of warm water will restore right conditions. I also watch the spot where the chick is pipping through. If dry, moisten it with the finger. The one big reason for taking out the dry chicks is that in struggling about over the eggs they turn so many pipped eggs over and the chick so turned very often smothers.

SAVING WEAK CHICKS.—Then too, it is said that a chick not strong enough to get out alone should be left to die. This I think is partly wrong. It never pays to take a chick from the shell, but poor shaped eggs, excessive dryness of the inner lining and other causes sometimes prevent a chick's getting away after the egg is pipped. Such eggs I crack clear around with the edge of the thermometer, breaking the outer shell only. If the chick remonstrates vigorously you may be sure it is worth saving. Generally nothing further need be done. However, if the chick still stays in the egg after four or five hours, the top or lid can be lifted off as bleeding will have then ceased. Again, you will find eggs pipped clear around but little pieces of the inner lining have been missed in the cutting around process and have dried so that the top of egg is firmly locked on. Such an egg should have the top removed at once or a crippled chick will result. And right here I might say that nearly all crippled chicks are caused by delayed hatching. It requires close watching and quite a little knowledge of the appearance of pipped eggs to tell whether help is needed and can profitably be given.

WARM WEATHER EGGS.—Beware of eggs saved in warm weather. I have just had a sitting of eggs from an Indian fancier, which on test showed many rotten eggs with well developed chicks in. This was a fifth day test. Another sitting from a Kentucky fancier who stated none of his eggs was over a week old when shipped, at the fourth day test showed nine eggs from 15 badly rotten with well developed chicks in. The Kentucky man stated the weather had run from 95 to 106 for the entire month during which the eggs were saved. Probably eggs were not collected till sundown and then kept in an ordinary living room or kitchen. In that case, with a weather mean even as low as 90, incubation was bound to start and continue for a number of days. I cite this because here are two instances which appear to give me a chance to get mad and demand satisfaction, but a little study of conditions shows that the sellers in both cases acted in perfect good faith and were supposedly sending perfectly good eggs. The only safe way in such weather is to gather the eggs hourly and get them into a cool cellar, turning them daily until ready to put into the machine. Along in May after the weather was quite warm, I had 30 eggs sent me from Indiana. These were all dated, showing some of them to to be at least three weeks old. Two tested out and 21 strong chicks hatched in the incubator. An inspection of unhatched eggs disclosed the fact that all the three-weeks-old eggs had hatched and those unhatched were fresh ones or nearly so when put in the machine. You never can tell, for according to rule and theory a poor hatch should have resulted from eggs of three weeks of age saved in very warm weather.

STOLEN NEST VS. INCUBATOR.—Just one more incident. A man brought me 300 Brown Leghorn eggs to hatch. Seventh day test showed 175 dead and infertile. When I talked with him he could not understand the matter, stating that several hens had stolen their nests and brought off nearly 100%. A little study reveals this situation; the weather was very warm. By his own statement he gathered eggs only at night, consequently eggs laid early in the morning had been under hens probably till three or four in the afternoon—and it is stated three hours will start incubation. The test revealed just such a condition. The eggs were not clear but looked as though the yolks were very dark, showing the germ had started and died. Now the hens that stole their nests and got the good hatches had a different set of conditions to work under. Biddy runs across the road in the morning, slips under a bush and in 20 to 40 minutes has laid an egg and is back with the flock. No other hen knows where this nest is. The shade of the bush keeps the egg cool all day. Next morning biddy comes back, settles down, turns around a few times, turns the egg or eggs over a few times, lays another and is gone. Here we have perfect care of the eggs from laying until the hen is ready to sit and explains the poor test of the eggs sent to the hatcher, and the good hatch of the stolen nests. Don't be too hasty to condemn your flock or the man who hatches your eggs. Look for causes and explanations and many problems will straighten themselves out. P. L. W.

Michigan.

Trouble With Ducks.

WE have been trying to raise several dozen ducks. The eggs hatched moderately well, but raising the young birds has been a failure. About half of them have died. They were started on chick feed and after a few weeks given wheat and corn. They have a pleasant, shady little run with a pond sufficiently large to give them good swimming room. They are being mothered by two hens. The ducklings seem to be weak and to feel the heat greatly. Every other day one dies. Some have trouble with their eyes, so that they are sore and closed up. Often one or two will seem too weak to walk. Could you give me some information regarding the care and feeding of young Pekin ducks?

Ohio. H. R.

I think the difficulty is in the feed. Ducks should not have hard grains till they are nearly mature. One of the best feeds for the first few days is bread crumbs and rolled oats, moistened with water or milk just enough to be crumbly. Mash for ducks should never be sloppy. In three or four days add bran and corn meal, and gradually change to a mash of as many kinds of ground feeds as you have. A splendid feed for growing and laying ducks is the following: Vegetables, one part; green stuff, one; beef scraps, one; low-grade flour, one; bran, two; cornmeal, three. Fine grit should be put in all mash for ducklings. Lack of it causes all sorts of digestive troubles. A pinch of salt in each mash helps make it a complete food, and a little ground charcoal once a week is thought by many to be good for them. Young ducklings are better off without water to swim in. Domestication has diminished their ability to indulge in promiscuous swimming without getting too wet and chilled. They should have drinking fountains into which they can not get, but with water deep enough to cover the entire bill. Wash the eyes gently with warm water till they can open them. Give them a grass run, a chance to get into the shade, and a warm dry place at night.

W. H. H.

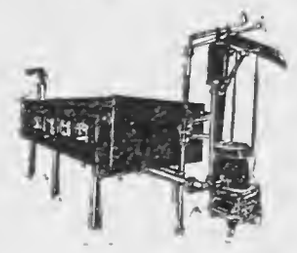
Hen Retains Eggs.

HAVING a hen so fat that she could only walk or rather waddle, and thinking she might have "leg weakness," and then be past any value I killed her. In her ovisac were six large soft-shelled eggs weighing 17¼ ounces besides the empty shell of another. The question arises in my mind, if these eggs had been fertile (I keep no roosters, so of course these were not) would there have been chicks in them? Would not the heat of the hen have started incubation? It is a peculiar case; has anyone had a similar one? F. T. J.

Rhode Island.

Fertile eggs retained too long in the oviduct may undergo partial development of the embryo and be anything but "fresh" when laid. One case is reported in which skin and feathers had partially formed upon an embryo within an egg that was removed from a hen after death. The bad odor of some new-laid eggs is also thought to be due to undue retention of the egg within the oviduct and the changes which it has undergone because of the high temperature. M. B. D.

"Do you drive your own car?" asked the expert motorist. "No," replied Mr. Chuggins, "I never drive it, I coax it."—Washington Star.



Capacities, 1200 to 20,100 Eggs
(Sectional Construction)

The cash results demanded by the practical poultryman are given by the Hall Mammoth Incubator.

Stronger, livelier chicks (and ducks) are invariably hatched by it. "Hall Hatches" grow into money quickest with the smallest losses, least trouble and expense.

The Hall gives many chicks you would not otherwise get. This higher average puts extra profits in your pocket. Because of the success of its users, its sales and re-orders exceed all others.

Big dividends are returned to its users. Shrewd business-poultrymen (and women) buy it on its record of results and on conviction of its superiority of principle and value. They invest in it because it pays for itself quicker and because its guarantee is all in their favor.

What size can you use? Do you want our helpful literature? Write us a letter giving details of your plans. Ask us to send our SERVICE SPECIALIST to help you get the right equipment and results—no charge—he may be in your section now or later.

PUBLISHER'S DESK

On June 25, 1913, I shipped Mr. W. H. Ruffhead, Irvington, N. J., by Adams Express, C. O. D., five cases of eggs at 25 cents per dozen, by previous arrangement. On arrival he wired me that he would not accept them unless I released the C. O. D. I released them. He kept writing and wiring for three or four days for more shipments, but I sent no more. He kept promising to pay in a few days, but did not. After threatening a complaint to the post office he sent me a check for $5 and said if I would not notify the post office he would send the balance in a few days. I have been unable to get any more since. The balance due me in $34. Can you collect it for me? T. P.
New York.

The above complaint came to us in November last. In May Mr. Ruffhead wrote the shipper that he had a $100 note due in three months, the maker of which was worth $30,000 in real estate over and above his debts. If the shipper would send him a money order for $66 and a receipt in full he would send the note by registered letter. Needless to say this proposition was declined for the reason that if it was offered in good faith, we see no reason why he could not borrow $34 on it at his bank and meet the obligation. We now have a letter from Mr. Ruffhead in which he says he is going to file a petition in bankruptcy and offers us some gratuitous advice in language which does not seem to be entirely friendly. Some of these good people seem to think that when THE R. N.-Y. requests a settlement of a subscriber's account it is interfering with things that are none of its business. Mr. Ruffhead is evidently of this mind. It is necessary at times to remind these people that every subscriber has a personal interest in THE R. N.-Y., and is entitled to the service of the paper in any way that it can serve them. In this particular instance the service does not materialize to the subscriber in dollars and cents, but the experience may have a cash value for other subscribers who may have an opportunity to ship produce to Mr. Ruffhead or to others of his kind.

I am sending you some literature from the Lexington Chocolate Company, 12-14 Lexington Avenue, Brooklyn, N. Y. From confidential information received here I think you will find this company is mixed up with the old parties who conducted the Franklin Incorporated Candy Manufacturers, New York. They promised a profit of 60% for investment in the stocks of the company. J. B. B.
Michigan.

Our reports confirm the information of this subscriber to the effect that the promoters of the Franklin Incorporated are behind this Lexington Chocolate Company. Some of the officers of the candy company were indicted by the Grand Jury in March last for alleged fraudulent use of the mails, and are awaiting trial. They may have avoided any criminal responsibility in the literature of the Chocolate Company, but nobody may expect to make 60% profit on an investment in any kind of hot air. There is no law against expectations, but the investor who tried to borrow money in a bank on this stock as collateral would learn the difference between value in hand and promoter's expectations.

Can you collect $1,500 on a note given me by R. H. McCready of Ridgewood, N. J., due May 4, 1913, and remaining unpaid? Mr. McCready is an ex-minister. He came into this place three years ago to sell stock for the Manhattan Properties Company, 347 Fifth Avenue, New York City, which has since failed. Mr. McCready was personally known to me and my family, and we relied upon his representations that the investment was perfectly safe, paying 6% profit. He had preached in our midst and personally guaranteed the investment, saying that he was not coming among us to offer investments that were not reliable. He said he was worth $11,000 or $12,000, and that he would be responsible himself for my investment. He gave me his personal note as an assurance of his promise. When due the note went to protest. After he got me to invest the $1,500 he came back and told me that the stock was advancing in price and that he would let me have 50 shares at the old price if I would take it at once, so again I believed him and paid $500. For this he gave me no note. When he was here he hired me to take him around, and he now claims that I helped him get people to go into the scheme. He is now trying to get some of the old dupes to invest in the Land and Credit Corporation, 24 Liberty Street, New York. He claims great things for this, just as he did for the Manhattan Properties Company. I am a poor man and need the money. C. B.
New York.

After repeated demands on Mr. McCready for settlement of of this account he came to us with arguments to show that he was not responsible for this subscriber's money or loss. For once we are afraid we were not polite to our caller. He probably was not impressed with our sense of hospitality. We fully expressed, in view of Mr. McCready's explanations to us, things to him personally that we do not wish to print. The Manhattan Properties Company has failed and the investment is a complete loss. The subscriber has yet the privilege of suing on the note, but Mr. McCready would probably set up the defense that the note was mere accommodation given without receiving consideration, and is, therefore, void and it is quite probable the court would take this view of it. At best if a judgment were secured, with the attendant expenses, the judgment would only be valuable if the collections could be made from Mr. McCready, and on his representations, collection of the judgment would be extremely doubtful. In our own minds, under circumstances of this kind, we hold Mr. McCready morally blameable for the losses to his parishioners, but if any of them repeat the experience we would be inclined to feel that they merited the result of their second experience.

George F. Cole, Boston, Mass., wholesale and commission dealer in fruits, vegetables, poultry and eggs, was sentenced to a year and a day at Greenfield jail by Judge Morton in the United States District Court for using the mails in a scheme to defraud creditors. This is the second time he has been in court on a charge of this kind.—Press Dispatch.

In view of Mr. Cole's record, we think he got off with a very light sentence. Most commission men who swindle farmers out of their produce have a way of escaping the penalty they deserve. But a jail sentence does not cure rascals of this sort and we predict that as soon as free, Mr. Cole will use the same old bait in perhaps a little different form to entice shipments from farmers. New England farmers will do well to be on the lookout for his literature about a year from now.

Several days ago I received a package with three neckties from the Crane-Watson Mfg. Co., Equitable Bldg., Boston, Mass. It had no card or anything on it, but the address of the company. It happened to be near my birthday, either by strange coincidence, or by their plan, and I supposed some one sent them to me. Now, I have a letter from them which I am enclosing. The ties would be dear at three for 50 cents. I am going to ignore their letters and keep the ties, which I shall not use. What can they do? I think it is an imposition and it seems to me as if they should be stopped. If I return the ties I am out postage as well as trouble. I thank you for your advice if you can give it to me, although out of your line. B. W.
Massachusetts.

This is the method employed by vendors of cheap razors for some time back, but it is new to us where neckties are concerned. B. W. is under no obligation, moral or otherwise, to either return the neckties or pay for them. In fact he owes it to the public to do neither, as the only way to stop this sort of imposition is to make it unprofitable to the schemers. Just so long as these people can send out cheap goods in this way and bulldoze those to whom they send the goods to pay them it will continue. Make such methods unprofitable and then it will stop. J. J. D.

Catarrh.

A MARE about 17 years old, teeth all worn out, has had a cough for some time and lately it is worse. It is a snorting convulsive cough; runs a little thin watery fluid at nose. She has two lumps, hard and smooth on the inside of her lips, lumps are about three-quarter inch in diameter. The discharge in late Winter was more yellowish. She eats whole oats but does not grind her food very well; skin rather rough, partly due to poor grooming. She stood a good deal all Winter in barn and was only used for short drives this Spring; runs in sheltered pasture with light grain when not being driven. She seems alert; manure sometimes almost washy and comes out in a heap. Opinion is desired as to glanders. J. B.

Employ a graduate veterinarian to make an examination for glanders, and if he does not find it present he can give the teeth proper professional attention. In glanders ulcers will be found upon the lining membrane of the partition between the nostrils, and grapelike tumors under the jaws. A. S. A.

Kicking Heifer.

I HAVE a valuable heifer that kicks badly when she is milked. I have tried strapping her legs, and used every other method that I could think of. She does not seem to improve, but on the contrary grows worse. Can you tell us of any method or device that will help to overcome the trouble? H. C. H.

Such a heifer should be sold to the butcher, as she seems to be incorrigable. We know of no other plan than giving a relished feed at milking time, and if necessary putting a wide strap around the legs, just above the hocks. You might also try the effects of a strap or rope tied around the belly, in front of the udder and a board put under that, lengthwise of the body. A. S. A.

Shrink in Milk.

I HAVE a good Holstein cow in good condition. About ten days before I turned her on grass she commenced to shrink in milk flow, and in one week's time did not give more than one quart. She did not gain when turned on good feed. She freshened February 5, is five years old and has been good until now; eats well and shows no symptoms of disease. U. B.
New York.

Shrink in milk commonly is due to garget, or to indigestion, but may be associated with any disease or ailment. Without an examination we could not confidently assign the cause in this case, but on general principles it would be well to have the cow tested with tuberculin. If she proves to be free from tuberculosis all milk secretion should be dried off, or the cow if fat should be sold to the butcher. Medicinal treatment would not be likely to help. A. S. A.

Goat With Bloody Milk.

ABOUT three weeks ago I purchased a Toggenberg doe. Her kids were then six weeks old and just weaned. Her milk seemed good for a few days and then we noticed a settling of blood in the bottom of the pitcher. We stopped using the milk, but milked her night and morning. The flow of milk has decreased and the amount of blood in it has increased so that now it is pink in the pail. We give her good pasture, plenty of water, and oats twice a day. She seems contented and happy. Can you tell the cause of her condition and the cure for it? B. D. J.
New Jersey.

Foment the udder with warm water three times a day and each night rub in a mixture of one part each of fluid extracts of belladonna leaves and poke root and six parts of warm melted lard or sweet oil. A. S. A.

Tumors.

WILL you tell me how to treat two tumors on shoulder of horse arising from neglected collar-galls. Cold water doused on them frequently seems to be helping some. The horse is being used right along without any noticeable trouble. The swellings (not large) are quite firm, and exude now no matter. W. C.

It is best in such cases to cut out the tumors and then treat as common wounds until healed. If you cannot have this done at present, paint the tumors twice daily with a mixture of one ounce of tincture of iodine and three ounces of extract of witch hazel. A. S. A.

Claims won't fill your silo

GET THE FACTS

It's actual *capacity*, not claims, not big-looking machines, nor big-sounding numbers that gets a silo filled.

You can easily figure any cutter's capacity. It depends upon the size of the throat and the number of revolutions per minute—*if* machine is otherwise able to handle the silage. The

BLIZZARD
Ensilage Cutter

is small, because so compact and simple, and its numbers don't run high because they represent the width of the throat—but when it comes to *actual work* the Blizzard *fairly eats up* the corn. Use a Blizzard and your silo will be filled slick as grease.

The Blizzard is easy running. Your farm engine will run it. Fills highest silos. Makes even-cut silage. Simple, safe, durable. Self-feed table. Almost runs itself. **Write for catalog and full particulars.**

The Jos. Dick Mfg Co.
Box 20 CANTON, OHIO

Harder Silos
Catalog Free

For 15 years the one Best Silo. Great improvements this year—better than ever. Solid as an oak; owners now laugh at storms. More durable than concrete, more profitable than tile. Massive strength, surprising solidity, perfect fitting and easy operating doors. The kind "Uncle Sam" uses.

It will pay you to write us today for free catalog of Harder "Quality" Silos.

Harder Mfg. Co., Box 11, Cobleskill, N.Y.

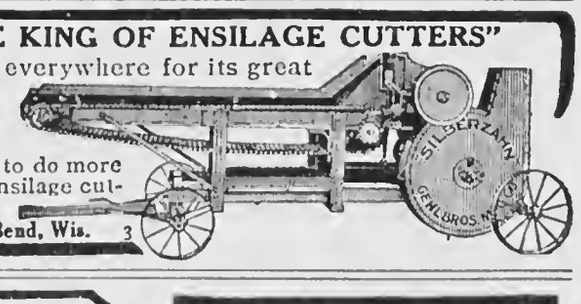
Light Running **Silberzahn**

"THE KING OF ENSILAGE CUTTERS"

is known everywhere for its great simplicity, strength and durability, its can't clog and safety features, its absolute supremacy among ensilage cutters. It stands the test of hardest work. **Guaranteed** to do more and better work on less power than any other ensilage cutter on the market. Write for catalog and proof.

GEHL BROS. MFG. CO., 107 S. Water St., West Bend, Wis. 3



Cut Ensilage With The Light Running "Papec"

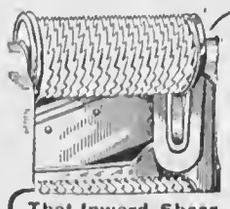
A 4 h. p. engine will run "The Wonderful Papec." It cuts and elevates the ensilage in a full steady stream to the top of the highest silo as fast as you can bring the corn to the machine. The

PAPEC PNEUMATIC ENSILAGE CUTTER

is simple in construction—easy to set up and take down—convenient to operate—gear driven—no lost power. Write today for illustrated catalog—sent **free.**

"It Throws and Blows"

PAPEC MACHINE CO., Box 10 SHORTSVILLE, N.Y.
25 Convenient Distributing Points in U. S.



That Inward Shear
If you cannot buy a Climax alone buy with your neighbor. Tell your thresherman to investigate its greater durability and convenience. If we have no agent or dealer in your locality, have someone get in touch with us at once.

That Inward Shear is a great saver of power. The knives are arranged to cut from the outer end toward the main shaft where the cutting power is greatest. Other wheel type machines cut the other way, pushing material to the outer end of knife. This feature of the

CLIMAX SILAGE CUTTER

fully explained in Free Catalog which also explains the advantages of elevating through our closed elbow—Save one man in the silo—Save power.

Products, Prices and Trade.

Wholesale Prices at New York.

Week Ending July 10, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914	1913
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.41 and $1.31 for B and C. Hotels and restaurants using two to three cans per day are paying 4½ to five cents per quart.

BUTTER.

Price on the better grades declined one-half cent, one result being a little increase in speculative trade. There has been a large volume of business in rather low scoring creamery at 24 to 25 cents. Demand for lower grades is slow, and prices cut freely to meet possible customers.

Creamery, extra, lb	26	@	27

Packing Stock	16	@	18

Elgin, Ill., butter market 26 cents.
Philadelphia, western creamery, 27½ cents.

CHEESE.

The market in better grades of whole milk has been firm, with a decided scarcity of fancy white. Reports from the west indicate a weaker market, especially in Wisconsin, which we may feel the effect of in a few days. Skims are in surplus and very dull.

Whole Milk, fresh, specials	11¼	@	11¾
Average fancy	14	@	14¼

Dalsies	15	@	15¼
Skims, specials	11	@	11½
Good to choice	10	@	11
Poor to fair	5	@	9½

EGGS.

The market is considerably unsettled, owing to the large proportion of defective stock, even in choice marks. The week has brought a one-cent advance on best nearby-eggs, free from damage. Large quantities of supposedly candled and graded eggs have sold around 20 cents, a heavy disappointment to the shipper. Part of the damage may have been done on the road, but it is evident that more careful candling aand grading will pay at the shipping end. If the buyers here have to do the grading, they have an excuse to discount the price—usually more than conditions warrant. The high-class buyers who want eggs running as nearly 100 per cent. good as possible, instead of 75 or 90 per cent., will not consider the poorly graded lots, though they may contain as good eggs as those that bring higher prices. The writer has often heard it said that grading does not pay, as one man's ungraded eggs often bring as much as his neighbor's choice, but has not yet found a case where the apparent discrepancy could not be accounted for in some common sense way.

Lower grades	15	@	18

FRESH FRUITS.

Receipts of new apples are increasing, but many are poor, wormy and windfalls, so that prices run low, often 25 to 50 cents per bushel. Peaches are in very heavy supply and lower, fairly good Carman, Belle and Mountain Rose having wholesaled at $1 to $1.25 per crate, and $2 about the top for choice. The cherry market was bad but improved the latter part of the week; strawberries, blackberries and raspberries poor, damaged by rain. Muskmelons low, except for the choicest, running uniform in quality.

VEGETABLES.

New potatoes much higher, choice from Long Island bringing $4.50 to $5 per barrel, and Jersey only 25 to 50 cents less. Onions generally higher, except some from nearby, which were defective. Cabbage in excessive supply and low. Tomatoes low, except some from Jersey, which brought $1 to $1.25 to $1.50 per box. A small quantity of nearby sweet corn is on hand, bringing $2 per 100 when choice.

Cough.

We have a pig two months old that coughs nearly all the time; it is quite thin. We bought three, one is two weeks older than the rest. We feed only separator milk and buttermilk; they all eat and are always ready for their meal. They have a large lot to run in on grass.
Pennsylvania. S. T. T.

Cough in a pig of that age probably is due to lung worms and if so there is no successful treatment, and the other pigs may become affected. A well-fed pig generally survives and outgrows the ravages of the worms. On general principles it is well to give a teaspoonful of turpentine, per 80 pounds of body weight of pig, in slop for three days in succession and repeat the following week. Isolate the affected pig. Tuberculosis may be present and that is incurable, but it cannot be determined without a tuberculin test by an expert. A. S. A.

Bent Knees.

Will you tell me what to do to cure a horse that is knee sprung and weak in both his front legs? I bought the horse, nine years old, recently and the owner said that he has been in that condition about two months now. I rub his legs at night with warm water. When pulling on asphalt or cobbles he stumbles, but while pulling on soft ground he gets along well. Do you know of any remedies or cure for the case? He is a valuable horse if his legs would straighten and get stronger. M. J.
New Jersey.

The horse is foot sore as well as bent in the knees and the latter condition is chronic and incurable. He may stumble less if you have him shod with flat bar shoes put on over rubber pads, as he has to travel on asphalt. If he continues to stumble he may improve if you clip the hair from the hoof-heads of both fore feet and blister them, one at a time, at intervals of three or four weeks, using a mixture of one part of powdered cantharides and three parts of lard for the work. A. S. A.

Abnormal Breathing.

What ails my cow? She breathes like a wind-broken horse. She is driven from pasture, but after a time she breathes naturally. I turned her on grass two weeks ago. She is seven years old, eats heartily, holds up in the flow of milk. We physicked her and have been giving aconite 15 drops. She will get her breath hard, then cough. E. L. R.
New York.

The cow probably is afflicted with tuberculosis of the post-pharyngeal glands, and that is incurable. To determine the matter have her tested with tuberculin. Any graduate veterinarian can properly apply the test. Meanwhile isolate the cow and do not use her milk. If tuberculosis is not present there may be pressure from an abscess or tumor due to actinomycosis (lumpy jaw) and that would require an operation by an expert. A. S. A.

Wound.

I have a horse which stuck a fork in the side of his front ankle bone. This happened three weeks ago. I have had the best veterinarian around here. He keeps her foot in a hot creolin bath, one ounce of creolin to eight gallons of water. I keep it hot all the time. The leg is not swollen, only a little around the ankle. This sore is suppurating freely. He does not give me much hope of saving the horse. He is talking of putting on a hot blister. He thinks it will be an open joint. Have you any suggestions to offer? G. S.
Massachusetts.

If your veterinarian is a graduate you should depend upon his skill and judgment in such a case. The blister may have to be used when the wound closes and lameness still persists. Meanwhile the wound should be covered with a dry dressing such as a mixture of one part each of iodoform and tannic acid and six parts of boric acid, covered with absorbent cotton and clean bandages. Renew the dressing once daily. A. S. A.

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

YOUNG MAN wants work on poultry farm; has had some experience. POULTRY, care R. N. Y., 333 West 30th St., New York.

SITUATION WANTED—Herdsman, single, specializing in Holstein cattle and certified milk, wants position; references. MARQUARDT, Westchester, N. Y.

POULTRYMAN, with years of practical experience, wants position where work and results are appreciated; triflers not wanted to answer. C. F. YAKE, Lebanon, Pa.

AN ENERGETIC, PRACTICAL MAN DESIRES position on poultry farm; desires to learn business; moderate wages. L. PHANEUF, 81 Hanson Place, Brooklyn, N. Y.

ORCHARDIST, experienced, desires position; apples a specialty; can begin work November 1st; best references. T. M. R., care R. N.-Y., 333 West 30th St., New York.

YOUNG MAN, graduate of Michigan Agricultural College, experienced, wishes position of manager or assistant of a truck and fruit farm or estate; can start at once; best of references. Address D. M. PURMELL, 18 Michigan Ave., Dorchester, Mass.

CITY MAN, bachelor, 41, some knowledge of horses but very limited, other country experience, wishes employment on scientifically managed farm; object, learn management details; small wages starting; reference; personal interview suggested. ECONOMY, P. O. Box 206, Madison Square, New York.

ALFALFA HAY. F. P. ERKENBECK, Fayetteville, N. Y.

WANTED—Stump or boulder blasting; charges reasonable. Address A. SIEBLS, care of A. J. Boyce, East Schodack, N. Y.

TIMBER LOTS AND POULTRY FARM for sale. M. W., care R. N.-Y., 333 West 30th St., New York.

FOR SALE—Two farms; one up-to-date chicken farm, 30 acres; buildings for 1,000 hens. Also a sheep and dairy farm of 150 acres. Five camp lots on Otsego Lake. K. E. WHITE, Cooperstown, N. Y.

WANTED TO RENT from six to 25 acres, small house; must be in good community, within reasonable distance of market or shipping center. R. H. T., care R. N.-Y., 333 West 30th St., New York.

IDEAL FRUIT AND POULTRY FARM, situated in Otego, N. Y.; nine acres; good buildings; furnace; city water, fine spring; fruit in abundance; two hen houses; part cash, balance remain on mortgage. R. M. AITKEN, Otego, N. Y.

FOR SALE—Dairy farm of about 151 acres, on State road, five miles from city of Newburgh; large house and out-buildings; large apple orchard and other fruit; price reasonable. Address O, care R. N.-Y., 333 West 30th St., New York.

FOR SALE—Boarding house, established fifteen years; accommodates fifty guests; with 128-acre dairy farm; will keep forty cows; milk station on farm; everything in first-class shape. Price, including growing crops, $11,000. Immediate possession; easy terms; photos and particulars on application. Address WILLOW BROOK COTTAGE, Wallkill, N. Y.

FARMERS' SECURITY BUREAU, NEW YORK Ageney Famous for Reliable Farm Help. No Branch. **SIDNEY SULLIVAN, Expert, 99 Nassau Street**

The FARMERS' BUREAU an agency exclusively for agricultural help. Only first class farm help and positions solicited. References Investigated. Scientific advice on farm problems. Dept. R, 150 Nassau St., N. Y. Phone, 5565 Beekman

DO YOU NEED FARM HELP

We have many able-bodied young men both with and without farming experience, who wish to work on farms. If you need a good, steady, sober man, write for an order blank. Ours is a philanthropic organization and we make no charge to employer or employee. Our object is the encouragement of farming among Jews. **THE JEWISH AGRICULTURAL SOCIETY, 176 Second Avenue, New York City.**

HUMOROUS

"I SUPPOSE you are saving up for a rainy day?" "No," replied Farmer Corntossel. "Out this way we pray for rain. I'm saving up for a drought."—Washington Star.

"HE who puts his hand to the plow," screamed the cross-roads orator, "must not turn back!" "What is he to do when he gets to the end of a furrer?" asked the auditor in the blue jean overalls.—Christian Register.

"DON'T you know you ought to be spanked? What do you mean by holding my watch beneath the hydrant?" "Why, you told Mr. Smith just yesterday that you had to soak your watch every once in a while."—Houston Post.

MOTHER: "Sometimes there are rude boys in Sunday school who giggle and smile at little girls, and sometimes little girls smile back at them, but I hope my little girl does not behave like that." Small Daughter: "No, indeed, mamma; I always put out my tongue at 'em."—Boston Transcript.

ONE of the guests at a wedding seeing a dismal looking young man, who appeared to be on terms of familiarity with the principals, asked: "Are you related to the bride or to the bridegroom elect?" "No," was the gloomy reply. "Then," said the guest, "what interest have you in the ceremony?" "Well," replied the young man, "I'm the defeated candidate."—Ladies' Home Journal.

MEN who sit still in the street cars while women stand and give as their excuse the assertion that women do not thank them when they do offer their seats will like this story: The man arose and gave his seat to a girl. "Oh, thank you, most kindly, sir," she replied. "Don't mind her being polite," explained a sad-faced woman. "I'm taking her to a sanitarium."—Kansas City Star.

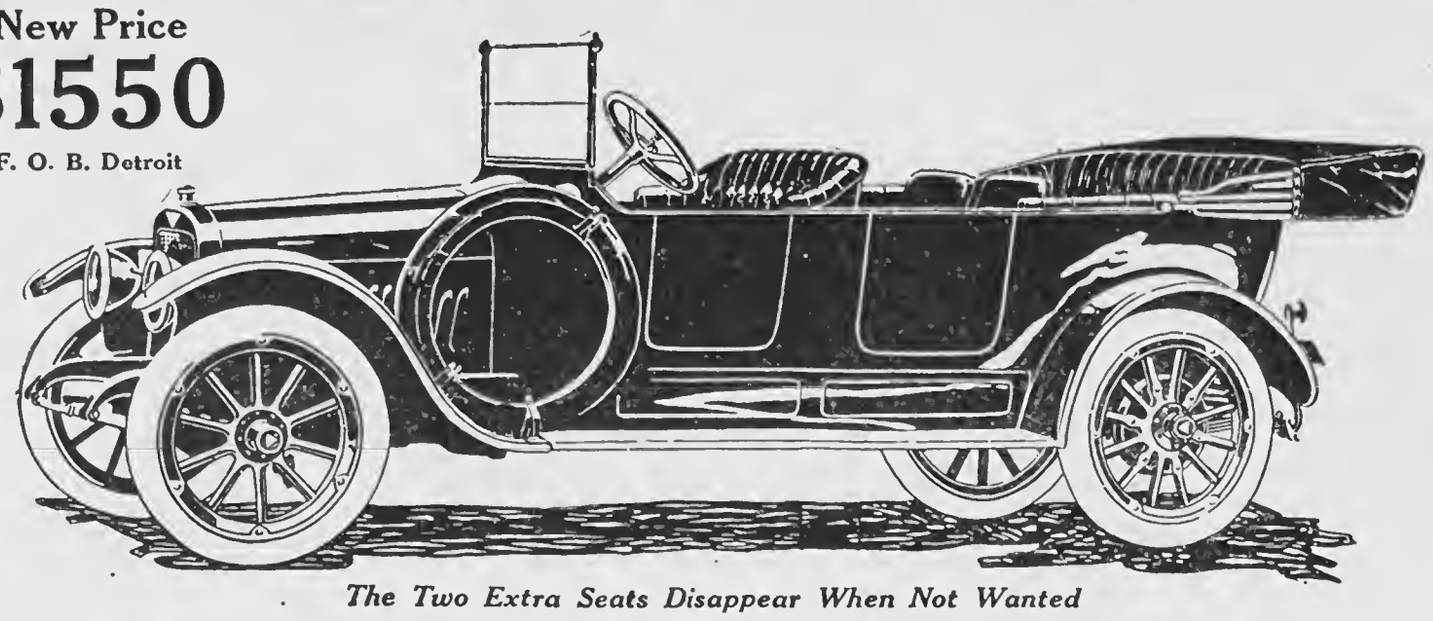
THEY had just finished taking a new film in a big German moving-picture studio near Berlin. Among the properties was a live stork which had been trained to reach out one of his long legs and shake hands with people. Everybody was gathered around the bird trying out his accomplishment. A little six-year-old girl was among them. The stork shook hands with her, too. Then she ran beaming to her mother crying, "Mamma! Mamma! he knew me again at once!"—New York Evening Post.

ROBERT had two little playfellows who were passing the afternoon with him. They finally began boasting about their parents and belongings. "My father," bragged Robert, "is going to build a fine house with a steeple on it." "That's nothing," exclaimed Louis, scornfully. "My father has just built a house with a flagpole on it." Sherman, who had been listening intently, was silent for a moment, then burst forth triumphantly: "Gee, that's nothing. My father is going to build a corking house with a mortgage on it."—Harper's Monthly.

SAM and Luke, browsing around, crossed the pasture. The Judge's bull saw them, and Sam beat him to the fence by a single stride with nothing to spare. Luke, a bad starter, didn't try for the fence; he stuck to the open. He led the bull around the field on the first lap, while Sam, from the fence, urged him to "a li'l bust er speed." On the second lap Sam exhorted him: "Run, niggeh—you ain' half runnin'!" The third time, Sam yelled: "Make has'e!" Luke risked all in his answer. "G'awn, man," he gasped, "you doan think Ah'm *throwin'* dis yer race, does yer?"—Credit Lost.

HUDSON Six-40 for 1915

New Price
$1550
F. O. B. Detroit



The Two Extra Seats Disappear When Not Wanted

Next Year's Gem Car

The new HUDSON Six-40—now just out—fulfils our dreams of the ideal car.

It is our last season's success plus a year of refinements. It has 31 new features. And the price—due to trebled output—is $200 less.

Our 48 engineers—headed by Howard E. Coffin—have now devoted four years to this HUDSON Six-40. And they now present it as the finest example of the coming type of car.

Note What It Embodies

You have wanted a Six, but all Sixes were costly. Here is a Six of the finest type for $1,550.

You have wanted lightness. Here is a Six, with room for seven passengers, weighing 2,890 pounds. We have saved at least 1,000 pounds—the weight of a car-full of people. All through proper materials and better designing, with no sacrifice of strength.

You wanted lower operative cost. Here a new-type motor saves you 30 per cent under former cars of similar capacity.

You wanted beauty. We offer you here one of the handsomest cars in the world—a distinguished car—a thoroughbred.

You wanted every convenience, every comfort, every new idea in equipment. We embody them all in this car.

A New Quality Price

You have felt heretofore that quality cars had to be high-priced. You have found no low-priced car to compare with them.

But here is a car built to accord with the highest HUDSON standards. It is built by Howard E. Coffin and his famous corps of engineers. Four years have been spent to bring every part to the finest point of refinement. It forms the last word in a quality car. And the price is $1,550.

Some 1915 Features

Distinguished streamline body.
"One-Man" top with quick-adjusting curtains.
Extra tires carried ahead of front door.
Invisible hinges.
Disappearing tonneau seats.
Dimming Searchlights.
Simplified Delco starting, lighting and ignition system.
Wiring in conduits.
Better carburetion.
Automatic spark advance.
Lock on ignition and lights.
Gasoline tank in dash.

Last year's HUDSON Six-40 met an overwhelming welcome. Men ordered 3,000 more than we could build. They offered premiums to get it.

We have met men's wants. Now, to meet their demands, we have trebled our factory output. And the saving effected—$200 per car—goes to HUDSON buyers.

Other cars will this year offer you many of the HUDSON attractions. These are the lines which the best future cars must follow. But you'll not find elsewhere these attractions combined with the HUDSON price. Go see our new model and prove this.

The HUDSON Six-54 is a larger model of this same-type car. It is big, impressive and powerful—135-inch wheelbase. The price is $2,350.

Hudson dealers everywhere have these new models on show. New catalog on request.

HUDSON MOTOR CAR COMPANY, 8064 Jefferson Ave., DETROIT, MICH.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

Vol. LXXIII. No. 4265. NEW YORK, JULY 25, 1914 WEEKLY $1.00 PER YEAR.

THE PRIDE OF THE FARM. Fig. 391.

A PERMANENT TIMOTHY MEADOW.

The "Clark" System Once More.

PART I.

TELL us how to start a permanent Timothy meadow—one that will last? The land on which we propose starting the Timothy is not strictly sod ground but played-out Alfalfa land. Alfalfa has been seeded twice with poor results. It was plowed last in August, 1913. N. W. M.
New Jersey.

Annually for at least 15 years we have retold the story of Geo. M. Clark's method of growing Timothy. Each year there comes a new set of questions which seem to make a new telling necessary. If anyone ever raised more hay to the acre than Mr. Clark we do not know where the records are. At any rate Clark's theory was sound and with modifications to suit conditions it is the best one we know of. Clark lived in Connecticut. The soil he cultivated was naturally the hard stony land so often seen in New England, grown up to brush and huckleberries.

THOROUGH PREPARATION.—That is the first principle of the Clark method. Taking such a field as N. W. M. tells about the first thing would be to kill out every plant now growing on it. The object of this is to make a *permanent* meadow wherein the Timothy once seeded so that the plants are started will grow for years—fed and producing their crop year after year like trees. In order to do this the Timothy plant must be free. Unless the weeds and tough old grass growing on the soil before seeding are fully killed out they will come back, take possession of the land and crowd out the new seeding. We all know what happens when we let cultivated land "go back to nature." Weeds and trash of all sorts crowd out the cultivated grasses and change the character of the sod. The chief reason why many grass seedings are so short-lived is because the old sod is not fully killed out and the tough old tramps work in before the young Timothy plants can make a sod thick enough to crowd them out.

WORKING THE SOIL.—The usual plan was and is to use a turning plow and turn the old sod or other growth on the field completely over. This put the grass and weeds out of sight. The under soil was turned up and certainly looked brown and clean and fit for a seeding. It is strange how many farmers have been fooled by the bottom of a furrow slice. After a thorough harrowing this upturned soil looks mellow and fit and clean, but the farmer seems to forget that a few inches below this seed bed are to be found the entire mass of weeds and trash which ruined the old sod or made the field a nuisance. This foul stuff is not dead. It will come to life in all its vigor at about the time the young Timothy plants are growing well, and being stronger than the new-comers these old plants will make their way into the new sod, and cannot be kept out. Thus the only way to make sure of a permanent meadow of the desired grasses is thoroughly to kill out the old plants before putting in new seed. In a short rotation this work would not pay. It is meant for preparing permanent meadow.

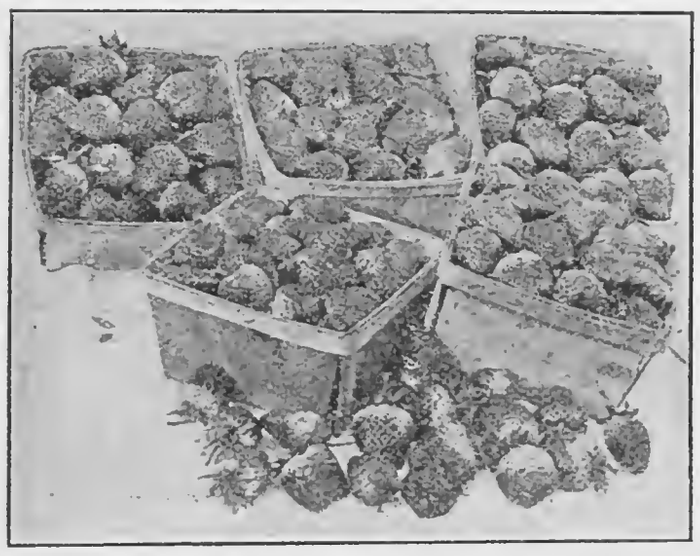
STIRRING THINGS UP.—That is what Clark tried to do. He said that grass and weed roots were not killed by burying them—they must be cut and thrown up and out where sun and air can get at them. This means a tillage tool which reverses the work of the turning or covering plow. The disk or Cutaway harrow does this. Imagine a steel pie plate flattened out to a disk. Cut out notches in the rim so as to leave saw-like teeth and you have the principle of the cutaway. Hold this disk solidly down into the ground and roll it along. The curved and notched rim will cut into the sod and as it turns lift out its narrow cut and give it a toss or shake instead of turning it over as the plow would do. Now we see what happens when a heavy Cutaway harrow with a number of these sharp disks is put on a sod with power enough in front of it to make it go at a good pace. These disks tear at the sod, cut out great chunks and toss them up and over instead of ripping over one long furrow slice. Often in working our own ground in this way the workmen have complained that the work was inferior to plowing because it did not look neat. The object is not so much to do a neat job as to put the sod up to the surface with its roots cut off. Plowing the sod over and fitting it for a seeding means perhaps five workings of the soil. The "Clark" method of tossing up the sod means from 15 to 20 workings and yet get the pay for your time at good wages when the grass starts. You chop it up one way and then go across the other way. Then you take a diagonal slant from one corner to the other and then try it from the other. As often as you see any green thing starting on that field you cut the surface up once more. July and August are the best months for doing this. The spring-tooth harrow is a good tool to help in this, but the lifting action of the disk or Cutaway is best.

DOUBLING UP THE CROP.

NEARLY all our market gardens have sufficient land to admit the planting of most crops in rows wide enough apart to enable the cultivation to be done mostly by horse power. The system of double cropping the land and rotation of crops as practiced by the most skillful and successful gardeners is about the same everywhere, and is as follows:

Beets and radishes may be sown together to advantage. As the beets require 60 to 75 days from the sowing of seed till ready for use, and radishes only 30 to 40 days, they can be cleared off before the beets crowd them very much. Sow the beets in rows 20 to 24 inches apart, and radishes between. This would make the rows of beets and radishes 10 or 12 inches apart. Sowing the seed of both first week in April, or as soon thereafter as possible, the crops will be cleared off by the first to the 10th of July, when a second crop can be planted. Of course, the crops are sold in an immature state—that is, before the roots have reached complete development. The land may be immediately replanted to celery, bush beans, or early sorts of sweet corn.

Sweet corn, muskmelons, cucumbers can be successfully grown together, and with considerable advantage to the melons and cucumbers. The ground should be furrowed, four feet apart one way. Make hills for the melons and cucumbers five feet apart, checker fashion. Plant two hills of sweet corn between the hills of melons and cucumbers. In the same row, and at the same time, either early or late corn may be used; and if it is desired to intensify, a little more radishes may be sown between the rows of corn and melons, etc. If the melon and



FLORIDA STRAWBERRIES PACKED FOR SHIPMENT. FIG. 392

cucumbers are not desired, bush beans can be grown between the hills of corn. To get the most out of the latter crops when grown together, the rows should not be over three feet apart for the dwarf corn and 3½ feet apart for the taller growing sorts. Plant two hills of bush beans between the hills of corn, planted at the same time. Radishes may also be grown between the rows of corn and beans.

Early peas may be followed by celery, or late planting of early sweet corn, beets, beans or turnips. Sweet corn, planted June 1, 4½ or five feet apart, with early celery between the rows, planted about the same time, can be handled to good advantage and with profit to the grower. Beans may also be grown between the hills of corn, making three money-making crops on the land at once. Soon as corn and beans have been marketed, clear off the stalks and vines, which will leave the land clear and in the proper shape for the cultivation and blanching of the celery.

Early cabbage and spinach may be grown together with profit, also lettuce and cabbage. One hundred to 120 days are required to bring early cabbage in, lettuce 65 to 90 days, and spinach 30 to 55 days, according to variety. The two latter crops can be cleared off before becoming crowded by the cabbage. Mark the ground out in rows 18 inches apart, plant early cabbage in every other row, and lettuce in the other rows. Beets and radishes may also be grown between the rows of cabbage. All may be cleared off by the time the cabbage is little more than half grown. Strawberry plants may also be grown between the cabbage rows, leaving the plantation in good shape for Summer growth of the plants when the cabbage is cleared off. Early cabbage may be followed by celery, bush beans, beets or an early maturing variety of sweet corn and beans.

Egg plant and tomatoes may have a late planting of lettuce grown between the hills or rows. Radishes may also be grown with these crops. Early plantings of lettuce and spinach should be followed by a root crop such as beets or carrots, or the ground may be planted to late tomatoes, or sweet corn and beans, or either one of the latter, as may be required. Lettuce can be grown to good advantage between the rows and hills of Spring-set strawberry plants to considerable advantage to the strawberry plants, as they will get more thorough cultivation during the growing period of the lettuce than they would be likely to receive if grown alone.

Early maturing cabbage, lettuce, radishes or beets may be grown between the hills or rows of pole Lima beans, and cleared off before danger of being injured by growth of bean vines. Radishes may be grown to advantage between the rows of bush Limas.

By procuring a kitchen garden seeding table, giving time of the various crops from the sowing of seed to the time they are ready for use, much can be learned as to how to get the most out of the land by double and triple cropping and by rotations. When the various crops are grown so closely together as outlined in the foregoing, it of course will be necessary to do all the cultivating with hand tools, such as garden hoes, rakes, weeders and wheel hoe. It is surprising how great a quantity of truck can be grown on an acre or two of well enriched soil when handled in the various crops in the manner suggested above.

Here is kitchen garden seeding table, showing about the number of days required from the sowing of seed, of the various vegetables until ready for use:

	Years		Days
Asparagus	3- 4	Beans, bush	45- 65
	Days	Beans, pole	65- 90
Beets, Table	60- 75	Cabbage, early	100-120
Brussels Sprouts	100-120	Cabbage, late	125-180
Carrots	75-120	Celery	125-150
Cauliflower	100-140	Cucumber	60- 85
Corn, Sweet	65-100	Endive	50- 75

SUPPORT OF ADJACENT PROPERTY.

I HAVE a neighbor who has opened a sand-pit. The pit is now 25 feet deep and they are within 20 feet of my line. They have four acres of land, which is very low on the street, and runs up to my line, which is high and valuable for building lots. This pit has ruined their place and is greatly depreciating the value of my place. Can you tell me how near they can *legally* come to my line, and is the place responsible for damages if they sell out? We are friendly neighbors, and I would like to remain on friendly terms, but it worries me to see them destroying their place and depreciating the value of mine; when it caves in it will ruin my building lots. H. H. J.
New York.

The best discussion of this matter is found in Reeves' book on real property. He states that there exists by nature the right of every landowner to have his soil supported laterally, in its natural state, by the soil or structure of the neighboring proprietor. When, therefore, one makes an excavation upon his own land, in such a manner that the sand, clay, or other material of the adjoining land will fall into the pit or be disturbed if not artificially supported, and there is no special contract or statute authorizing him to so dig, he must shore up or otherwise support the other's soil, so as to retain it in its natural condition; or he will be liable in damage for the resulting injury. And this is true regardless of the location, contour, or constituent materials of the neighboring land, in so far as these exist in a state of nature. Thus, the lower owner upon a hillside must support the soil of the upper owner, to as great an extent as is necessary to retain it in its natural and undisturbed condition. And, whether the properties be on a hill or a plain, the amount of such support required will depend, of course, upon the quality of the soil, grading from nothing or almost nothing in rocky sections to a heavy burden in places where the soil is sandy or from any other cause readily movable. This right to the lateral support of natural soil is absolute, unless restricted by contract or statute; and when it is interfered with, all that its owner needs to prove, in order to establish a cause of action, is that he has suffered damage becaues of such disturbance. He need not show that the excavation which caused his soil to cave in was done in any careless, negligent, or unskillful manner. You should, therefore, notify your neighbor in a friendly manner that he is endangering your land and that you will look to him to pay any damage which may be caused by his negligent excavation. He would be liable and not the land. M. D.

"A DOOR that needed to be open and would slam has been fitted to a small staple and a hook put on the woodwork back of the door when open. Now it stays open when we want it to," says J.

THE ART OF HAY-MAKING.

Working to Advantage.

"MAKE hay while the sun shines" is a good adage, but, like many other such sayings, does not contain all the truth or lead to the very best practice. I want to present a few facts which have a bearing on the subject of hay-making. King says the amount of water evaporated through the leaves of the plant and necessary to produce one pound of dry matter in the crop is from 270 pounds in corn to 576 pounds in clover. If these figures are trustworthy, then a two-ton per acre clover crop has evaporated through its leaves 2,304,000 pounds, or 276,480 gallons of water. The crop has been grown in 60 days, and if we grant, for the sake of argument, that the use of water was equal in all stages of its growth, we have a daily evaporation of 38,400 pounds, or 4,608 gallons. This is more than two times the total weight of the green crop. If the power of the clover plant to discharge water could be preserved, three or four hours of sunshine would fit the greenest, heaviest clover for the mow. This large amount of water is given off mainly through numerous minute openings in the under side of the leaves, very little of it from the stem or stalk.

Again transpiration is much more rapid during the daytime than at night; in fact, may be almost totally checked in rainy weather or on dewy nights. The fact that plants acquire water during the night and lose it during the day is shown by the wilting and rolling of the corn leaves on hot, dry days, and their regaining freshness and turgidity during the night.

What of our common haying practice in the light of these facts? It is a common practice to mow in the morning, when the crop has the most water in it. The leaves, subject to the fierce heat of noonday, quickly wither and lose their power of exhaling moisture from the stems, and the crop must lie in the burning heat for hours while the moisture is slowly dried from the woody stalks. This makes the leaves so dry and brittle that they shatter off in handling, and the value of the crop is greatly impaired.

Now, suppose the mowing be done in the afternoon. The crop contains much less water, and the leaves, unburned by the noonday sun, retain their freshness and power to exhale moisture, and the hay is really making faster during the late afternoon than at midday when it seemed to be drying so rapidly. Grass cut in the afternoon will not get dry enough to be blackened by the dew, and once stirring the following morning with tedder will let the air through it and dry it so it can be taken up with the loader or windrowed before the leaves become dry and brittle in the scorching midday sun. There is a vast difference between air-dried and sun-burned hay. Many farmers burn the life out of their hay, and then wonder why their stock do not do well when they have all the hay they can eat. Much nutriment has been lost.

Many farmers with small acreage want to cure their hay in the cock. This method makes good hay, but it involves much extra work. Hay made as above outlined, by afternoon mowing and air drying, retains the nutritious leaves and preserves its flavor and goodness wtihout extra handling. While modern haying tools have greatly expedited and cheapened the heavy work of haying, they have not relieved the farmer from thonghtful planning of his work if he is to secure the best results. A good crop gains value through intelligent handling.

Ohio. F. L. ALLEN.

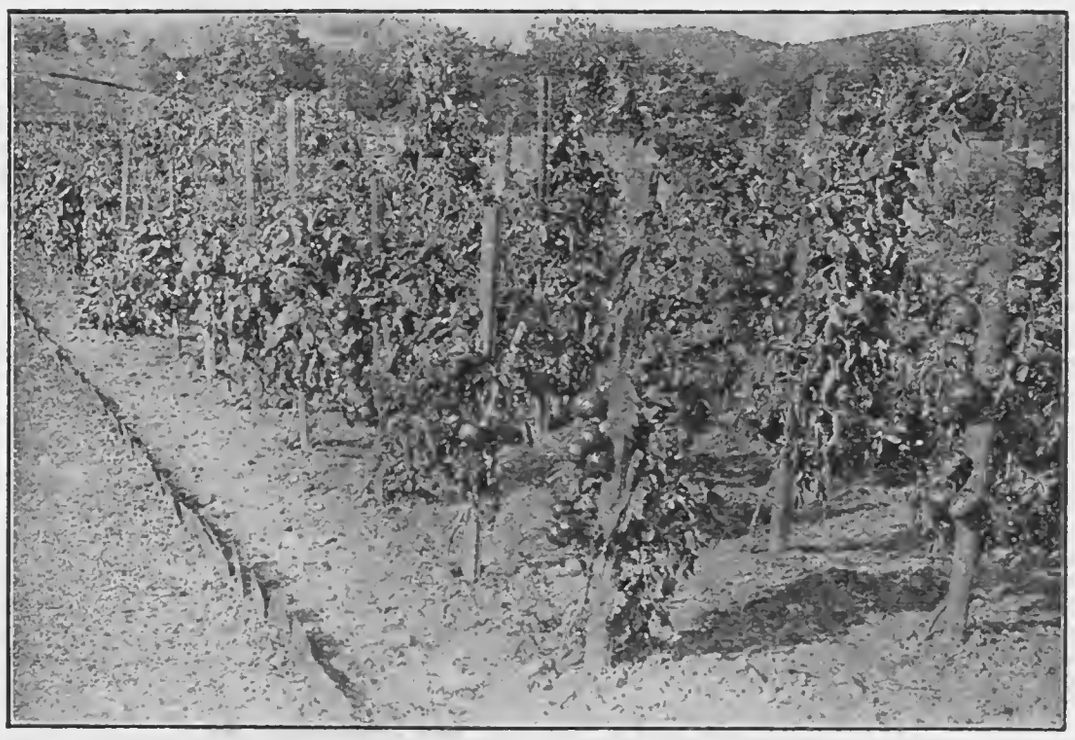
GIVE THE STOREKEEPER A SHOW.

IT may be that the consumer of the actual food stuffs pays $1, of which the actual grower gets but 35 cents; and it may be occasionally a reasonable thing to do to have only the parcel postage stamp between the one and the other, but occasionally, not often, I pay as a matter of convenience willingly a profit to a grocer who pays rent, or interest and taxes, because I can get everything at the store. A country store sells gloves, eggs, rope, flour, bananas, candy, stepladders, mowing machines, and the proprietor feels a sort of responsibility to have his goods all satisfactory. He sends for broken pieces of machinery for you, gets about anything one orders, from a white mouse to a white elephant. The middleman, so much criticized, slandered, vilified, etc., really is a man of great business ability, and gets often a scant living, for rent and interest on mortgage and taxes are large consumers of that 65 cents.

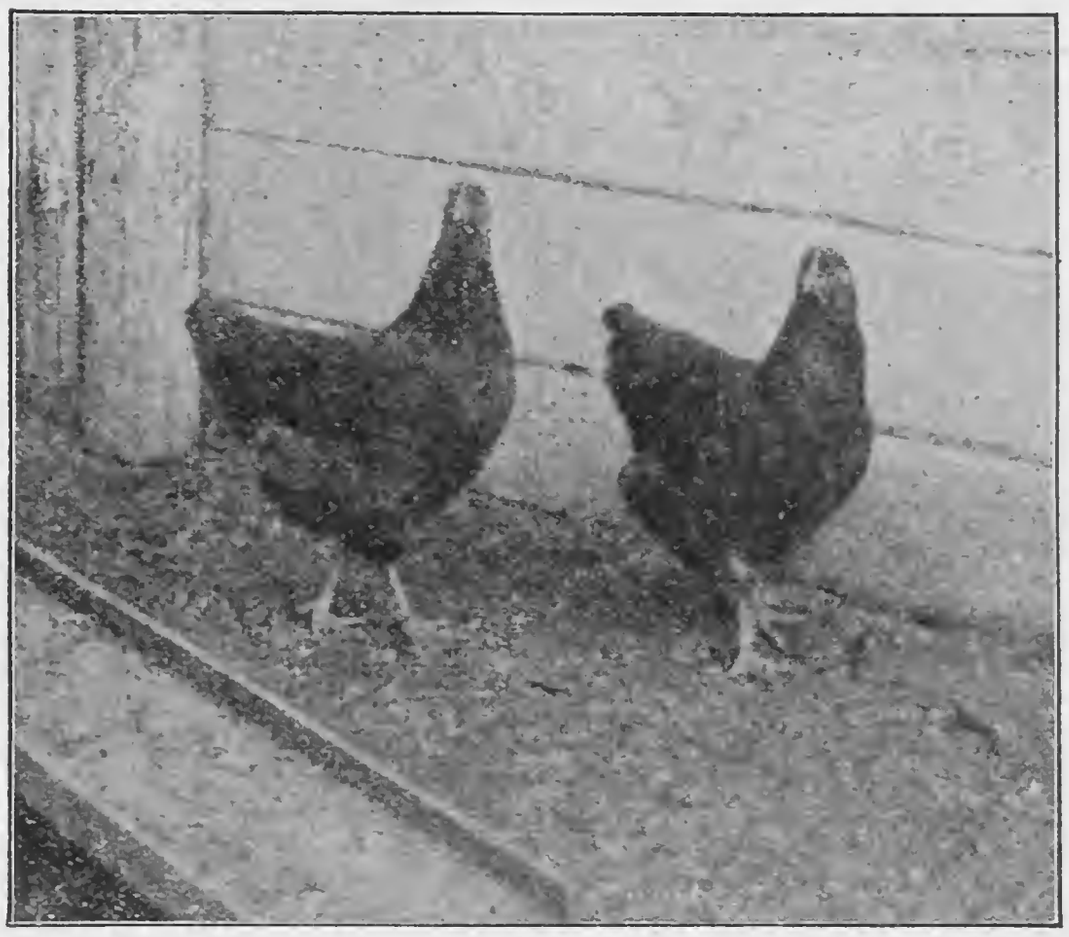
The man living on interest from mortgages is the one to rail about; some turn their mortgages every year so as to get as high as 25 per cent. The dividend getters of the railroads are clamoring for more. The owner notices every change in a rise in value to put on more rent, and the interest neither slumbers nor sleeps, but keeps steadily at it 24 hours a day and seven days a week. The mortgagee replaces the loan as often as he can for a consideration, having a broker to share a bonus with, and an attorney to search a title, which has been so well searched that it's as well known as New York on the map. Don't scold the grocer too hard; he has his worries and expenditures. The loafer living on an income is the absorber of 60 of the 65 cents. It is easy to overlook the other side of the middleman's business, which may not be a rosy one.

A housekeeper cannot easily write to Java for coffee, to Guiana for pepper, to Brazil for nuts, and Greenland for walrus shoe strings, and the mails would be overflooded with small packages. The distributing points are best, and the corner grocery. The fancy-goods shop next to it is even better to patronize than a department store requiring a half day's journey. ELBERT WAKEMAN.

Maryland.



A PATCH OF TOMATOES, WELL STAKED. FIG. 393.



R. I. REDS AT THE THORNDALE EGG-LAYING CONTEST. FIG. 394.

AN expert pruner tells of this side of his work: "I am making about 70 cents per tree, and prune about eight trees per hour, so I don't have much rest for my right arm. All the cutting is done with hand shears (I have used the saw three times in two weeks), so you can judge the condition of the trees." Let's all go to "Summer pruning. This is only one side of it, for not one man in 1,000 could earn such wages.

LIVE STOCK WITH ORCHARDING.

IN connection with our orchard interests we are planning to go into the dairy business for the purpose, largely, of manufacturing fertilizing for the fruit trees. We are not able to buy manure at all, so that if our herd of cows only pays expense of itself and gives us manure for profit we will consider it profitable. Our plan is to feed the whole year and save all manure, both liquid and heavy matter, using only a building for the exercise of the cows and where nothing of value can be lost. Do you think that a plan of this sort can be carried out to advantage or is it visionary? We have now over 30,000 fruit trees growing, and we are planning to plant about 5,000 more each year until we get our 800 acres well planted. The matter of fertilizing is the one hardest to solve. This plan I am working on I thought would not only solve that, but would give employment to the men we must keep during the Winter, saving some expense in that way. We can clear new land for hay ground and for corn for the silo. I thought this could be rotated with Alfalfa, clover and corn, so as to keep the ground right. A. A. L.

Traverse Bay, Mich.

Send to the experiment stations at East Lansing, Mich.; Madison, Wis.; Minneapolis, Minn.; Ames, Iowa, and Wooster, Ohio, for barn plans and bulletins on silo building and care and feeding of cattle. This plan of keeping live stock to fertilize the orchards is right for some conditions—not all. On most large orchards cover crops and chemicals are used to maintain fertility. Crops like rye, vetch, peas or clover are plowed under each year with the use of lime. On stony land such treatment will usually carry the orchard on to bearing age. After that some plant food—chiefly potash and phosphoric acid—will be needed. In some parts of Michigan wood ashes can be bought cheaply. This will give a good supply of potash. In some sections it is possible to buy waste bones at a fair price. These can be crushed in a bone mill and used with the wood ashes and with the cover crops, providing the cheapest food for the orchard.

Where live stock is kept we find usually a herd of dairy cows, a flock of sheep or a bunch of beef cattle. The dairy cows require most capital and most care. Milking and handling the milk will interfere with the orchard work. In order to keep up the herd you must keep a large number of young stock or buy fresh cows at a high figure. Dairying is a business by itself, and you will have to put in an expensive outfit and hire some high-priced men if you keep cows enough to eat up all your feed. The more common plan on large orchards is to buy sheep and steers in the Fall, fatten them through the Winter, and sell in Spring or Summer. This will provide a large amount of manure for the orchard, give Winter work for the men, yet not interfere with orchard work in Summer. On your large place, unless you have some special market for dairy goods, this feeding sheep and steers with cover crops will probably be better than dairying.

THE PICTURES.

FLORIDA STRAWBERRIES.—The picture at Fig. 392 shows the way strawberries are packed in Florida for Northern shipment. This photograph was taken at Elmer, in that State. These berries have a long, hard journey and the expense of packing, icing and transportation is considerable. It is therefore necessary to have them packed firmly so that they will make a solid bed in the box, and not shake about too much. When we see these berries taken out of the ice crate in this city it seems a wonder sometimes that they could make the long journey as they do. They must be handled with great skill at the start in order to carry them through.

EGG-LAYING "REDS."—The picture on this page, Fig. 394, shows two pullets entered in the Thorndale laying contest by Allen Jenkins of Virginia. This gives a good idea of the correct egg shape for Rhode Island Reds. These pullets are leading in the contest, and have made an excellent record, and are bred for egg pedigree. In addition to being excellent layers, they would also rank as show birds, and would probably score at least 92 points in the show ring. We hope to obtain from time to time good pictures of the leading pens in these contests, with a fair idea of their score, so that a reasonable comparison can be made.

STAKED TOMATOES.—A good method of staking tomatoes is shown at Fig. 393, this page. It is possible for any one to grow this crop after this plan, if proper pains are taken to select strong plants to begin with, and have the soil rich and strong. Thorough culture must be given, and proper pruning of the vine, so as to keep the lower limbs off the ground, and induce the vine to make a strong upward growth.

FARMERS' CLUB

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Asparagus Culture.

I HAVE a muck swamp, and I have been told asparagus will do well there. Will you tell me what soil needs to prepare it for asparagus? I have mangels on it this year, and was going to put potatoes next year.

Dutchess Co., N. Y. B. H. T.

Asparagus will grow on most any kind of soil, and will yield good crops on heavy soils. But for the production of asparagus for market, particularly on a large scale, a deep, sandy loam of good fertility is much to be preferred, as it is not only much more easily tilled but is warmer and earlier, which is quite important with this crop. Soils upon which pools of water will lie after a rain, or under which the subsurface water is near enough so that the roots of the plants are likely to penetrate it, are unfit for asparagus and must be avoided. Such a soil can of course be made fit for the growing of asparagus, provided it is suitable for the purpose in other respects. A thorough system of tile draining, at sufficient depth below the surface, will draw off the water so that there will be but a minimum of risk of damage to the roots. If the water has been well drawn off, so there is no danger of the roots becoming water-logged, and other conditions are favorable, this land should produce good crops of marketable asparagus.

K.

Market for Evaporated Apples.

CAN you give any information as to markets for evaporated apples, cores, skins, etc.? We understand that much of the refuse is exported and made into champagne. If this is correct, could you give us address of one or more firms that we can take the matter up with, as we are trying to put an evaporating plant in here this season? Can you tell us anything as to prices usually paid the farmer for his fruit? H. W. Z.

Pennsylvania.

The best markets for placing stocks of evaporated apples, cores, skins, etc., are found in Wayne County, N. Y., which is the leading section for this phase of the fruit industry, and in which many of the heaviest dealers have their warehouses. Sodus, Williamson, Ontario and Wolcott are much interested in this industry, Sodus heading the list with over 400 cars of this class of fruit released last year. All the dealers buy everything in the dried fruit line in any quantities. The chop apples are mostly exported and made into cheap wines and drinks. The cores and skins are made into cider and jelly. Germany also uses chops for a cheap drink, but not champagne. All the dealers in the fruit belt are direct exporters.

The farmer receives varying prices for his fruit, depending on the kind of season and grade of fruit. This year the prospects are that the grower will receive from 20 to 25 cents per hundred pounds for paring apples and 15 cents per hundredweight for chop stock. The prospects also are that the dealers in this section will pay about six cents per pound for prime quality evaporated fruit, with more for extra choice; $1.10 per hundred pounds for cores and skins, and one-half cent per pound for chops. These are estimates on the contingency that normal conditions ensue in the maturing and harvesting of the crop. Wayne County is perhaps the greatest county in the world for evaporators devoted to the dehydration of apples. A. H. P.

Rye on Poor Land.

I HAVE about three-quarters of an acre of rye, sown in light, sandy soil; has nothing put on it for years. The rye was sown without any manure, and is about up to my knees. Would you advise me to turn this under? I have three acres aside from this, all in poor condition, light, sandy soil. What would you advise me to sow in the Fall so as to turn it under for Spring? O. A. W.

Ulster Co., N. Y.

Probably this soil lacks both organic matter and lime. Plow this poor stand of rye under and use 1,500 pounds or more of slaked lime per acre. Then sow a combination of two bushels of buckwheat, three pecks of rye and two pounds of Cowhorn turnips per acre. The buckwheat and turnips will be killed during Winter, but the rye will come in for a Spring manurial crop. By plowing this under and using fertilizer you will get your land into fair condition.

COMING FARMERS' MEETINGS.

Summer School of Agricultural and Country Life, Massachusetts Agricultural College, Amherst, June 30-July 28.

Annual Poultrymen's convention, Massachusetts Agricultural College, Amherst, July 22-24.

Georgia State Horticultural Society, Summer meeting, Griffin, Ga., August 5-6.

International Apple Shippers' Association, twentieth annual convention and apple exhibit, Copley-Plaza Hotel, Boston, Mass., August 5, 6, 7.

Thirty-ninth Annual Convention of the American Poultry Association, to be held at Chicago, Ill., August 8th to 15th, 1914, inclusive.

Northern Nut Growers' Association, annual convention, Evansville, Ind., August 20-21.

National Dairy Show, Chicago, Ill., October 22-31. The following meetings and conventions will be held in connection with the show: American Association Creamery Butter Manufacturers, Oct. 26. Holstein-Friesian Association of America, Oct. 26. International Milk Dealers' Association, Oct. 26 and 27. Conference, Secretaries of State Dairymen's Association, Oct. 27. Official Dairy Instructors' Association, Oct. 27. National Dairy Union, Oct. 28. American Dairy Farmers' Association, Oct. 28. Council of the National Dairy Show, Oct. 28. National Association of Creamery Managers and Owners, Oct. 28. American Jersey Cattle Club, Oct. 28. National Association of Ice Cream Manufacturers, Oct. 28, 29 and 30. International Association of Dairy and Milk Inspectors, Oct. 29. American Guernsey Cattle Club, Oct. 29. Congress of Marketing, Oct. 29. Milk Producers' Association, Oct. 30.

Annual Show of the Paterson, N. J., Poultry, Pigeon and Pet Stock Association, November 18-21.

Indiana Apple Show, Tomlinson Hall, Indianapolis, Ind., November 18-24.

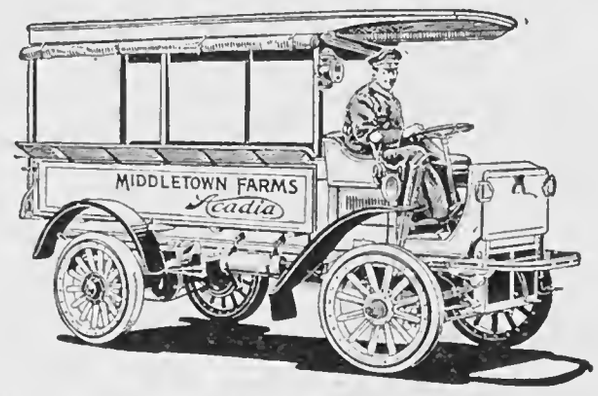
Reach Your Market With The *Autocar*—Save Freight



Middletown Farms Ship Products by *Autocar*

AS a quick and economical means of transportation, the *Autocar* Delivery Vehicle is now being used on farms all over the Eastern section of the United States. Dairy farms, truck farms, stock farms, fruit growers and farmers in general, have found that the *Autocar* brings old markets within easy reach and gives them new markets for their products which they could never reach with horses alone.

The Autocar

"Used in Every Line of Business"

An example of the value of the *Autocar* to the farmer is furnished by the experience of Middletown Farms, of Middletown, Del., who have used an *Autocar* for the past *four years*. They say:—

"We have run an *Autocar Delivery Vehicle* since October, 1910. This car has needed but few repairs and has given very satisfactory service.

"Before we bought our *Autocar* we used to ship all our products by rail from Middletown to Wilmington, Del., a distance of 25 miles. We make anywhere *from one to three trips every day, carrying 1½ tons each trip.* Of course we could never do this with horses.

"We have run our *Autocar* from 75 to 150 miles a day and its steady, reliable service has been of great value to our business. We now cover a route about as follows: leave Middletown at 7 A.M. and go to Earleville, Md., a distance of about 13 miles. It picks up the cream at that station and goes to Cecilton, gets the cream there and comes back to Middletown. Round trip 26 miles. We then go to Odessa, get cream and return. Round trip 7 or 8 miles. We then load the car and go to Wilmington, a distance of 25 miles each way. We get to Wilmington between 12 and 1 o'clock. We have made the run to Wilmington in 1 hour and 35 minutes with a full load."

What the Autocar has done for the Middletown Farms and is doing for other farmers it can do for you. Write today to Dept. R for the new Autocar book. It is worth reading.

THE AUTOCAR COMPANY, Ardmore, Pa. Est. 1897

Suggestions For Hair Dressing

Becoming and Unbecoming Effects

By Edna S. Knapp

A LITTLE woman of six said the other day: "When my hair gets longer, mamma is going to do it a different way. I don't like it the same every day." Some people do, there is Marie who has worn her beautiful wavy hair practically the same way for years, with

THE WORST POSSIBLE EFFECT.

the coil high or low as fashion dictates. Floris likes variety, she tries all the new styles and can wear any of them. On my last visit to them, Floris, who is the housekeeper, spent three-quarters of an hour doing her hair in an elaborate and very becoming manner, while Marie, who worked in the post office, put breakfast on the table. Yet Floris was hurrying, for this new mode took her an hour and a half when she first learned it.

Do you want to know how to make the best arrangement of your tresses? This is what Nan has just done. First she took her hand mirror and, sitting down before her dresser, took account of stock. If you try it at night, be sure you have a good light at each side. Everything that goes to make up appearance has to be studied, one doesn't mind admitting defects just to herself, being known, they can be remedied. This was the result of her study: height, medium; look taller on account of a long neck; complexion, good but pale; face, oval, but looks large unless framed softly by her hair; profile poor, head flat, no one feature especially prominent; hair a little thin at the temples; forehead so high that it would be well to cover it a little. She especially likes a low coiffure, it looks well in front and in back, but a profile view of any she has tried, proves dreadfully unbecoming.

All the new styles call for a low coiffure with great quantities of curly hair arranged well over the face. They are charming but few have natural hair

AN IMPROVEMENT IN FRONT.

enough to get the right effect. Most of us have straight hair, while apparently there are no styles for straight-haired people. I wonder why.

Nan's next step was to study the catalog de luxe of a Fifth Avenue hairdresser. It is a beautiful book, about everything dealing with hair, countless beautiful arrangements of wavy hair are pictured. It tells the laws of becoming arrangement for seemingly all types of women. Nan spent a good deal of time with the catalog, then finally wrote for advice, which is given freely, giving a full description of herself. The answer came promptly, courteously advising her to study the catalog. Thus thrown on her own judgment, she did study the catalog some more, and at last made up her mind. She has been wearing a modified pompadour, the short hairs around her face curled back from her face, and a coil at the right height to give a good profile line to her head. The new arrangement called for brushing down and cutting in "bang" effect the troublesome short hairs about her face, these were to be curled down to cover her high forehead. A parted pompadour of waved hair with a soft "basket weave coil" suited her. To do this, it was necessary to get a three-stem switch. The hairdresser's prices were low for the quality of his wares, but Nan's purse was low, too. The "basket weave coil" proved rather troublesome to learn and arrange so on ordinary occasions, a "figure eight" twist looked well. This was kept rather flat and the top of the coil went high enough to give a good outline to her head.

Now, having decided to alter her style of hair-dressing, it was necessary to wash her hair to get it out of the way it had been going. Hair has habits of its own,

ARRANGED BY A HAIR DRESSER.

you know. Nan uses tar soap with a little borax in the rinsing water to make her hair fluffy. She made the mistake once of putting in too much borax, but will not do it again. Some of the new head washes are much easier and quicker to use. Nan gives her comb, brush, side combs and hairpins a bath when she washes her hair. Nan is able to keep her hair in order ordinarily by washing it once in two weeks, brushing it a few minutes at night and giving her scalp ten minutes of massage with her finger tips, using a circular motion. In the winter, once a month for washing the hair does very well, with a dry shampoo of talcum powder once in a while.

Straight hair has a beauty of its own, in my humble opinion, if it is well cared for. It can be made nearly wavy by careful brushing and arrangement in loose, soft effects. It is almost wonderful what a difference the style of hairdressing makes. I asked Vivian to pose for some photographs to show this. Vivian has about the prettiest straight hair I know, soft and lustrous and almost wavy. The photographer was not rushed at the time so took a good deal of pains to get the effect wanted. The first view shows the worst possible effect gained by straining the hair back into a tight coil. Not even house-cleaning would excuse any such arrangement.

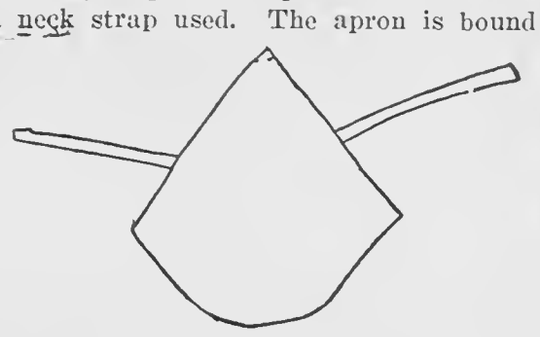
The second picture is the way she ordinarily wears her hair, and suits her exactly. This is the same hair and the same amount of hair as in the first view. The difference all lies in the way it is handled. Vivian's hair is long but it is not unusually thick. She is a past mistress of the art of making it look abundant. The third picture shows the arrangement a Boston hair-dresser preferred for her. The coiffure was the result of that lady's effort. It is more stylish according to present modes, but I do not like it as well as the second view. Although Vivian has straight hair, like the rest of the feminine world, at times she wears it curled. One is likely to look more intellectual with straight hair, but curly hair softens and changes the whole face.

Bangs are beginning to come in again, our English cousins call them "fringes." I suppose the reason is that the close hats and automobile bonnets of the day are so trying to many faces. You can buy a front-piece and wear it with a boudoir cap, if you don't get up in time to arrange your hair before breakfast and want to look as if you did. Seriously, boudoir caps have their uses. I noticed a beautiful elderly lady in the hospital one day this Spring; she was wearing a negligee of tan-colored flannel covered with rosebuds in Dresden effect. She had on a boudoir cap of lawn to match, trimmed with pink ribbon and lace. This seemed such a sensible fashion, you know how untidy your hair will get when you have to stay in bed.

You can even buy a wig to match your costume if you want the latest absurdity. Many of the styles of past years are in vogue, only arranged in lower effects. The mail-order houses carry in stock basket puffs, Psyche knots, two or three small puffs, and the coronet braid. Not nearly so many rolls are worn and nearly all the coiffures are moderate in size. Anyway, the extreme styles look like "her Thursday afternoon out." The style Janice Meredith wore is again popular for evenings. Very few evening arrangements of hair are worn without a headdress of some sort. Most show a band or bandeau of ribbon-covered lattice work worn either plain or with a chou of chiffon at one side. Some have a small ostrich feather at one side, others show feathers at each side. All match the dress as a rule. Some pretty headbands are of filagree. The general style of these accessories reminds one of an Indian maiden with headband and single feather. You can get hairpins now to match your hair. They are not expensive. The best are silk-covered. A well-dressed woman is supposed not to let her hairpins show.

EDNA S. KNAPP.

THE WELLESLEY APRON.—Has the Wellesley apron been described in your columns? It is pretty and practical and very easy to make. It consists of a square yard of unbleached drilling with one corner gracefully rounded. This is for the bottom. The opposite point is the bib, and may be pinned in place or cut off and a neck strap used. The apron is bound



all round with a contrasting color and has strings of the trimming. I made some once with stenciling as decoration. As it hangs on the bias it drapes gracefully and is the easiest to iron of any cover-all pattern I know. The picture is all the pattern one would need. K.

THE SIRE: "What would you think if I told you that at your age I never disobeyed my parents or teacher?" The Son: "You'd lick me if I told you what I thought."—Nashville Tennesseean.

∴ Hope Farm ∴

A FARMER should feel at peace with the world after supper on Sunday night. Fourth of July had come and gone, and the danger from fireworks had gone with it. The rain and fog had been bad for haying, and the crab grass and weeds had worked into our wet ground, yet thus far the season had been a good one for us. So, after supper, I was not disposed to fight with anyone. Very likely I should have come out better if there had been more desire for battle. I wanted to see how the beets were growing on the lower field, so with the little boys to follow and Fritz, the mongrel dog, to lead the way, we started across the road and down the little hill by the pasture. My little Airedale friend considered this mission so far from danger that she did not think the journey worth while, so she curled up in front of the house. We looked over the beet crop and examined our trees and then started back. Fritz went running across the field at the suspicion of a woodchuck. There is a wet spot in the field, so I climbed over the fence and walked along the stone wall in the pasture. The big black heifer raised her head and took a good look at me—then slowly moved my way. She is a big, heavy animal—the daughter of our old cow. We expected great things of her, but she has developed into a great beefy animal, unruly and mean. I should have remembered this, but she seemed good-natured enough as she approached, and I got off my guard. She came up slowly, and I put out my hand to see if the strap was on her neck. Quick as a flash she lowered her head and dived under my arm. Her head caught me on the side like a battering ram. I was standing on a round stone, and as I slipped my left leg curled under and my ankle twisted. Down I went flat between a post and a big stone. I could not get out, and my left leg was twisted. Then that big black brute seemed to know just what to do. She stamped with her front feet and tried to rip me with her horns. She seemed mad with rage, and came at me like a tiger, ripping, butting and stamping as if I were the "enemy." I thought that Florida cow that Uncle Ed and I bought was about the limit for fighting, but this New Jersey heifer was like Jack Johnson compared with a very ordinary citizen.

The Hope Farm man has faced several serious situation and had much time for reflection, but events never moved quite so rapidly through his mind as when he lay pinned between that post and rock with that maddened brute stamping and ripping at him. All I could do was to get her by the horns with both hands and try to hold her head away. On the ground near me lay a big stone. If I could get hold of this I could pound her over the jaw—but it was six inches beyond my fingers and if I let go my grip those horns would be free! If you want to know what people think of in such a situation I can give a few facts. First, there came into mind the absurdity of this fight. The heifer could gain nothing by killing or maiming me, as she was bent on doing. It was a foolish thing for me ever to trust such a creature, or give her the chance she had taken. As I lay there trying to hold her off I remembered that scene from "Quo Vadis" where the giant struggled with the bull until both were exhausted. It was hard for me to realize at first that the heifer was in earnest, but she grew fiercer as she fought, and I found my strength going! Then I suddenly realized that unless I could get help I was gone. On my feet I could have handled her, but she had me where I could not move. Then I thought of the little boys—one 10 and the other seven. Up to this moment I had not thought of risking them in such a battle, but it was now or never. So I called them to help, not knowing what they would do. Most boys and women and many men would have screamed or fainted or stood still—deprived of thought. My boys let out a call for the Airedale, picked up the first club they could find and came on. That heifer had wrenched one sharp horn loose and was slashing at me, when suddenly there came a sound such as an energetic man who seeks to please his wife makes when he beats a carpet. That sharp horn flashed within a couple of inches of my face. Out of the corner of my eye I saw Redhead and Towhead standing on the bars hammering that heifer with their war clubs. Perhaps you have read Rider Haggard's story of the African chief who stood at the head of the stairs with his battle axe and kept the great company at bay! Well, little Redhead had something of the same spirit as he balanced himself on that rail and made base hits on that heifer's neck! Flesh and blood could not stand that pounding long. The heifer finally backed out of range, bellowing and shaking her head, but before I could get on my feet she put down her head and came for another charge. Then there was a flash of gray color and little Airedale was at her throat, while Fritz had her by the heel. It is the blue blood that

A Redhead and a Box of Marshalls. Fig. 399.

goes to the seat of danger! The dogs soon had her in the center of the pasture and I got over the fence a little bruised and shaken, but very much wiser than I was before. The little boys went up to the house to receive congratulations and little Airedale sat with her wise head on one side only regretting that she did not have more of the fun.

The big heifer goes into beef. I have had two or three cows that picked up this habit of fighting, and they were always dangerous. One of them broke loose and got into the lane where our folks were walking. This brute attacked a woman and pinned her against a post. We cut the horns off, but as soon as her head was healed she resumed her hitting and crushing. On a farm like ours, where there are children at play, an animal with such habits and disposition is a constant danger. This big, plump heifer will make fine beef. One would think that some of these "white hopes" could eat a few steaks from her and then handle Jack Johnson with ease! At any rate she goes for beef, and here comes the singular thing about it. In spite of all this talk about a meat shortage it is a job to sell this big heifer. The local butcher will not touch her. There are no slaughter-houses left, and the dressed beef people will not bother with single animals. You can only sell to peddlers or "independents," and take what they see fit to offer. There are several silly Congressmen who, each year, introduce bills which would compel every farmer to raise two or more beef animals each year. Thousands of us would raise such animals at a loss, even at fair prices, and when we tried to sell them we should have to just about give them away. Wait and see what we actually get for my big heifer!

The Hope Farm Scrubs.—They did not do quite so well in June, but it is our duty to report progress without any complaint or apology. Here is the record:

	May	June		May	June
No. 1	21	7	No. 6	25	19
No. 2	22	19	No. 7	13	11
No. 3	23	22	No. 8	19	18
No. 4	21	19	No. 9	22	23
No. 5	28	21	No. 10.....	19	19

There were 15 eggs laid outside the trap-nests, so the total was 183. It is impossible to say which hens laid these 15 eggs. No. 1 may have laid some of them, or No. 5 may have laid several more than the record shows. I spend no time worrying about that. The scrubs laid 183 all told in June. Let us see how they compared with the blue bloods. Here is another table:

Record for June.

Hope Farm Scrubs.....	183
Average—all pens	170
Tom Barron's Wyandottes.....	166
Best P. Rocks (all breeds).....	192
Poorest P. Rocks (all breeds).....	146
Average all Rocks.....	165
Best Wyandotte (all breeds).....	202
Poorest Wyandotte (all breeds).....	115
Average Wyandotte (all breeds).....	153
Best R. I. Red.....	211
Poorest R. I. Red.....	97
Average R. I. Red (15 pens).....	146
Best Leghorn	249
Poorest Leghorn	117
Average Leghorn (34 pens).....	200

Thus the scrubs beat the average performance of every breed in the contest, except the Leghorns. There is one pen of Silver Campines. They laid 185 eggs—two more than the scrubs. Out of 82 pens there were 51 below the scrubs in the June total. Starting at the extreme tail end of the procession—there are now 12 pens behind them. On individual records they fell down a little. No. 5 laid 49 recorded eggs in 61 days, but this is behind several birds in the contest. No. 1 and No. 7 ought to be ashamed of their record unless those outside eggs belong to them, but we find no fault. These scrubs were in very bad condition when the contest started. They all had colds and most of them had been starved and jammed about in the live poultry market. Their egg record really starts from about March 1. They lost about 100 days at the start. I figured that the best they could do by July 1 would be 800 eggs. They actually laid 815. My figures are 950 by August 1. They have done far better than I ever expected, and the lesson I hope they will teach has hardly been started.

A Combination Crop.—The little picture at Fig. 399 shows a couple of Hope Farm crops—a Redhead and a box of Marshall strawberries. Both are high in color, with good foliage and healthy fruit. One helps grow the other. I think every farm should adapt itself to the best crop combination—suited to the soil and the temper of the farmer. Some soils are well adapted to fruit, but would fail with grain or potatoes, while others are not at all adapted to fruit or truck. Some farmers ought to be surrounded with children while in other cases it would be a mistake to let a child come on the farm! The best sort of farming is done when the crop combination is right. Redheads and Marshall berries suit us well.

H. W. C.

How to Get Lumber at Mill Prices Write to us. We will send you our prices which will surprise you. Mill prices on bright dry lumber shipped direct from our Yellow Pine mills. Prices far below what you would pay your local lumber dealer. Lumber of a better quality than usually sold from the retail lumber yard. Get our prices on small orders as well as large ones. See the savings. The capacity of our Yellow Pine mills is over 75 million feet per annum, and we carry a stock of over 25 million feet of dry lumber from which to fill orders. All goods shipped for free inspection.

Home Owners Carpenters Contractors Post yourself on mill prices before you buy. We will quote wholesale prices on all material to you. Special bills sawed out. Get our estimate before you place your order.

Mill Work We can furnish Doors, Sash, Trim, Moulding, Porch Work, Hardwood Flooring and everything that goes into your building.

Club Orders We ship to two or more parties whenever requested. You can club with your neighbors and get carload rates. Big saving on small orders.

Send No Money!

We will ship direct to any responsible party on approval. You can unload and inspect every piece of the shipment before paying us a cent.

Write Today Write to us now for full particulars. We can save you money and furnish you with guaranteed grades of lumber. Your name on a postcard will bring our mill price to you, and all particulars of our liberal method of doing business. Write today.

E. Frank Coe Fertilizers

1857 THE BUSINESS FARMERS' STANDARD FOR OVER FIFTY-FIVE YEARS 1914

Plan Now For Midsummer Seeding to Alfalfa Fall Seeding to Wheat, Rye and Grass

GIVE your Alfalfa the abundance of Phosphoric Acid and Potash that it needs, but remember also that while Alfalfa takes its Nitrogen from the air, *after it is well established* a moderate quantity of quickly available nitrogen is necessary to give the young plants a vigorous start before the root nodules develop.

In **E. Frank Coe Fertilizers** you get the right proportions and right kinds of plant food for your Alfalfa.

When seeding down to Wheat or Rye with grass, remember that you must supply sufficient plant food for two crops; otherwise your Wheat or Rye may be a success but your grass crop may be a failure.

Be sure therefore, to use fertilizers containing sufficient plant food to give Wheat or Rye and grass a vigorous start this Fall and also containing plant food that will become available next Spring and Summer, thus insuring profitable results from both crops.

Seeding to permanent mowings is best done late in August or early in September, without either Wheat or Rye. In this case use a heavier application of seed and a generous application of **E. Frank Coe Fertilizers.**

We have many different grades and kinds of **E. Frank Coe Fertilizers** adapted to every variation of soil and local conditions. If you will advise us about your soil and crops we will give you our honest opinion as to which fertilizers will give you best results.

You ought to read our booklet "Seeding to Grass and Clover." A copy is yours for the asking, without charge, of course.

THE COE-MORTIMER COMPANY, 51 Chambers St., New York City

Flower Growing For Women

Is It A Profitable Business?

Answered By Paul L. Ward

I READ an article on flower culture in THE R. N.-Y. and thought you could help me a little. Could you tell me where flower culture, for business, is most successfully carried on? I have grown Asters by thousands for four years or more, but find I can grow them easier than I can sell them. I have grown some fine large flowers and have been quite successful in my own way, but to grow flowers of perfection and specialize is quite another thing. I live in country and have read and know quite a little of hortieulture and general farm work. This is a sad country for gardens, corn patches or anything that wants to grow; we seem to be in a frost belt; every year from June 5-14 there are frost indieations and again August 21 to September 10 sometimes everything goes. Could you suggest any good locality that calls for market flowers, and is there a place where I could work and learn the ins and outs of flower culture in a business way. MISS E. L.

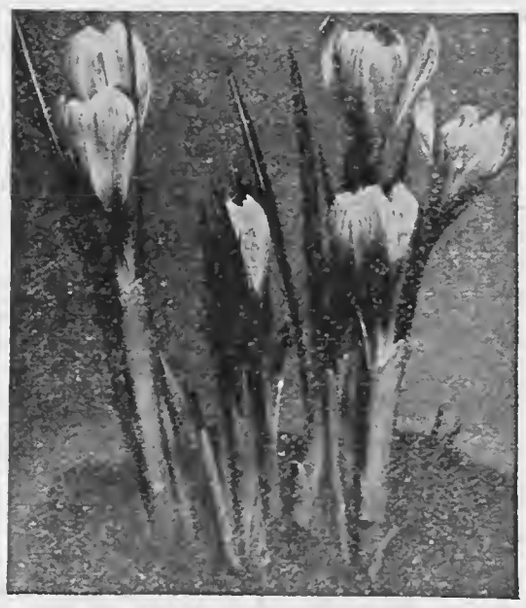
Western, New York.

THE PROFIT IN FLOWERS.—After handing a florist a dollar for a dozen fine carnations or making a similar expenditure for other flowers, the purchaser is likely to think how fine it would be to be the seller of those same flowers. The seemingly splendid prices received for almost everything in the floral world leads many to enter into the business of selling or producing market flowers, or both. In the first place, the prices paid for flowers are not high. They are extremely perishable products, expensive to grow in perfection and subject to all kinds of calamity. Such being the case, only one who has a great liking for flowers, a known ability to produce them and market them, should attempt to make a living thereby. Like poultry raising, the profits will come largely in proportion as the one engaged in the business loses sight of the almighty dollar and throws heart and soul into the work for the work's sake. It is a business you cannot turn over to a hireling and sit by and draw in the returns to the cash drawer, but you must be everlastingly on the job, and like it.

SELECTING LOCATION.—The beginner who wishes to make an independent start may well select a location in a town of 5,000 or upward, where he or she can obtain plenty of good land, preferably on the main road to the cemetery and as nearly central as possible. The factor of competition must be considered. If there are already local florists, it would be well to ascertain quietly if they were pleasing the people. If so, try another place, as I believe it is foolishness to try to build up such a business in competition with one who has the business and is giving satisfaction. On the other hand, if no competition exists or of a harmless sort, you can be reasonably sure of success.

CHOOSING SPECIALTIES.—Having chosen a location, choose the phase of floral work you will enter. The general florist trade requires some capital to start, at least a small greenhouse and some knowledge of designing, for funeral work, society functions, weddings, etc., are the main market for strictly flower work. If you lack the ability to do design work, the growing of potted plants can be taken up. This phase of the work is not so much in competition as the growing of cut flowers. A good idea for this is to make it a point to have some blooming plants in first-class condition every day of the year. From December 15 to March, primroses and Cinerarias are wonderfully salable at from 25 to 50 cents each; from January to Easter, all kinds of potted bulbs, hyacinths, tulips, Narcissi, etc., find ready sale. Specimen geranium plants are very popular. The single geranium, Mrs. E. G. Hill, is a splendid sort to grow into specimens, sometimes producing ten or more clusters at once, with nearly 100 flowers to a cluster, and the clusters measuring about 14 inches around. These go quickly at 50 cents each. Calla and Easter lilies are quite popular with the better class of buyers. For Summer potted plants there are always the geraniums, Verbenas, marigolds, Gloxinias, tuberous rooted Begonias, and Fuchsias, which can be easily grown and had in bloom during the warm months. For Fall, potted Chrysanthemums, Obeoniea primroses and ferns are popular. And we must not forget that grand plant, the Cyclamen, taking nearly 20 months to flower from seed but well worth the time and trouble. It sells from 25 cents for a plant with a single flower up to $3 each for plants literally smothered in bloom and in seven-inch pots. The list of potted plants is long, but the above are all popular, easy to grow and easy to sell.

HOW TO SELL.—Now for a selling campaign, having grown your plants and being ready to market them. First, get attractive stationery, the very best, for your product goes to a class that demands the best. Then write a personal letter to the teacher of every Sunday school class in the city, the chairman or chairwoman of all flower committees in different fraternal societies, each minister, and all persons who, for various reasons seem likely to be lovers of flowers. The giving of potted plants to the sick is a universal custom and it pays and pays well to cater to this demand both in price and quality. Many of these classes and societies are limited to 25 cents for each person who is sick. You can easily have a line of plants to sell at just that price. Lots of children will come in with ten or fifteen cents for a plant. Don't turn them away. A single Narcissus in a four-inch pot will make you a good profit even at 10 cents, and two in a pot for 15 cents. Cater to all comers in price but never lower your standard of quality. You have no idea what the advertising effect might be on your business to send out a bunch of sleepy carnations at half price just to keep them from being a total loss. Your entire florist business may be



A POT OF CROCUSES.

judged and found wanting by some one from that bunch of carnations. Throw all wilted and inferior stock into the furnace. Never sell a plant, no matter how well it looks, that you know will go to pieces the next day from having been in bloom too long. Your customer is entitled to at least a week of bloom, and except for funeral work only freshly opened flowers should be sold.

There are a lot of flower growers who have no greenhouses, who have no cold frames and little or no capital. These are the growers of Summer flowers, Gladiolus, Aster, monthly roses, pansies and many others, including a long list of perennials. It is much easier to produce these flowers than the greenhouse kinds, and correspondingly harder to find a market for them. Local demand will always take a certain percentage of them if they are first-class, but the large cities must be depended upon to consume the main crop, and it is practically useless to send anything but the very best to a city market and expect to get a living price. In certain flowers there is always a glut in season and only the best is used at all. Growers of the following three varieties of Gladioli find a good profit by getting fine stock onto an early market. They are, America, Augusta and Mrs. Frances King. Dahlias are coming into favor and when well grown, carefully packed and shipped are profitable. Asters, most widely grown of Summer flowers, never glut the market very badly because it is so hard to produce first-class flowers. The finest Asters are grown under glass by disbudding, where they are not injured by violent storms. The growing of Gladioli is increasing rapidly and as yet the gladiolus is little known to the general public. You can both sell the flower and produce an increase from the bulb so that they are doubly profitable, and they are as easily grown as potatoes. Yes, the growing of flowers and flowering plants for market is profitable if one is able to produce the finest quality and become known as a grower of fine stock.

Michigan. P. L. W.

Good Words.

I AM very much pleased with the issue of June 27 of your paper. It is a decided improvement on an already excellent paper. R. H. S.

Connecticut.

THE R. N.-Y. always was the best farm paper printed and since the Woman and Home Department has been enlarged it is almost perfect. I would be pleased if C. Allis or his wife would tell us just how she makes the curd for the cheese, and how long it can be kept before putting in the press. I tried with junket tablets and got it too soft. C. T.

New York.

Mrs. Allis tells about this on page 952.

THIS week's issue is absolutely "bung full" of good things and I have seldom enjoyed the contents more or desired so much information. A. F. A.

I HAVE taken your paper over a year and enjoy it very much. My husband never cared to read much, but now on Sunday he takes THE R. N.-Y. and reads it; says he thinks it a very good thing. MRS. P. S.

New York.

I WANT to say just a word of appreciation of THE R. N.-Y.; even in this western country it is more helpful than any other paper we have found. I only wish there were a paper dealing with Pacific Coast conditions, half as reliable and readable. MRS. R. W. WILLIAMS.

I WROTE you early in Spring in regard to fertilizer on an acre of good bottom land. You advised certain fertilizers. I followed to the letter, results so far best corn in the neighborhood, by 50 to 100 per cent. It is higher than I can reach and beginning to tassel and this in spite of the greatest drought ever known here. I have cultivated with one-horse cultivator, every 10 days. No rain on it since it came up, but one shower that just laid the dust. E. T. T.

Illinois.

R. N.-Y.—We gave you a sure combination of chemicals, though it might not pay a profit with low priced corn—one part dried blood, three parts fine bone, one part muriate of potash.

I DO appreciate THE R. N.-Y. and your straightforward course of exposing fraud, and the household department is a great addition. Among all the magazines I take THE R. N.-Y. comes first.

MRS. ALISON W. FALCONER.

Massachusetts.

The Bright Side.

WALT MASON, the prose poet, gets after the Ben Davis apple as follows:

Last Summer, when the hot winds blew, and wilted things on every hand, and when the sun, in skies of blue, shone down and blistered all the land, we mortals raised a bitter wail, and cried, "In this there is no sense, for all our cherished crops will fail! Oh, drouth disastrous, get thee hence!" Had any moral highbrow guys attempted to convince us then that back of all was purpose wise, we should have jeered and jeered again. But now that theory is fulfilled, for we're informed ten thousand score Ben Davis apple trees were killed, by that fierce drouth, to bear no more. Ben Davis trees are standing dead throughout this glad and fertile land, and we regret the things we said because we did not understand. So, let's be patient after this when trouble dogs us, close behind, for sorrow's but a cloak for bliss, and threat'ning clouds are silver-lined.

You have probably known people who have to be told exactly what to do. They are faithful as fate but have no imagination or initiative. Hearst's Magazine tells of a man who owned an animal show. One day, when the show was in New Jersey, I went out to Chicago to arrange some business. While I was having dinner, a telegram was handed me. It read: "The leopard has escaped. Prowling about the town. What shall I do? Peter." Pete was one of those fellows who had to have explicit directions to do anything, even in the emergency. He was always afraid of making a mistake. I rushed from the table and sent a reply. "Shoot him on the spot," I wired. Being unusually busy, I forgot all about the affair until about two hours later, when I returned to the hotel, and another telegram was handed me. It proved to be from careful, conscientious Pete, and asked: "Which spot?"

MY little girl is just beginning to go to school and does not know much about arithmetic yet. The other day the teacher gave her an example like this:

Teacher: "If you had $3 and I should give you $2 more, how much money would you have?"

Alta, aged six: "I should think I'd have four bushels." MRS. E. W. P.

Vermont.

Digging Potatoes with an IRON AGE

is like finding money because the work is so easily and economically done. You can dig in one hour all that a market wagon can carry to town. Saves time, saves labor, gets all the potatoes, helps you get to an early market when the price is right.

Four styles from which to choose the one that suits your conditions best. You pay for, and your horses draw, only what you need.

We have been making Diggers 10 years and know what to build for this work. Our booklet tells the whole story in an understandable way. May we send it?

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York
HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 60 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

THE big rascals and their spineless creatures who wrecked the magnificent property of the N. Y., N. H. & H. Railroad have put their thieving fingers into thousands of homes where THE R. N.-Y. is read. This railroad's stock was a favorite investment in New England, and was bought largely by people who desired a solid and sure income. Few railroad stocks in the country were bought so freely as family investments, because the public had the utmost confidence in the men who were supposed to control the road's finances. It now appears that these respectable men sat like dummies and did just what J. P. Morgan told them to do. Instead of "directing" they merely ratified schemes of robbery which—the Interstate Commerce Commission says—cost the railroad at least $90,000,000! The Commission says of the present outlook:

The splendid property of the New Haven Railroad itself will be called upon for many a year to make up the drain upon its resources resulting from the unpardonable folly of the transactions outside the proper field in which its stockholders supposed their money was invested. But honesty and efficiency of management of this property of the railroad only will undoubtedly in time restore its former standing.

We hope that our friends who have suffered because of this rascality will finally save their property. But what of the men who have so shamelessly betrayed their trust? They ought to be compelled to replace what was stolen, and the ringleaders among them who are left alive should be put in jail and kept there.

*

ON page 890 you say that opportunities on Eastern farms are superior to those in the West. If this be true the natural questions are why are Eastern farms being abandoned? Why is the price of land less than half what it is here, and why are not your farmers taking advantage of some of these great opportunities? W. M. O.
Iowa.

To answer your last question first—they are; thousands of them. Some of the most productive and profitable farms in the country are within 100 miles of the Atlantic Coast. The soil of these productive farms has been worked steadily for more than 200 years. Acre for acre they will produce more corn, more wheat, more potatoes and more hay than Iowa soil, while these crops will sell for twice as much per bushel, or ton, as the Iowa products! No good farms at the East are being abandoned. There are some rocky and steep farms which never should have been cleared. They never would have been touched if the first settlers had known what lay beyond them. These naturally unprofitable farms are now going back to the forest, though many are still used for pasture. Some excellent farms are unoccupied but not abandoned. These farms in the past supported large families and made money for their owners. They will do the same for other farmers if they can be worked with spirit, and if the farmer can have fair capital. One difference between Western and Eastern farming is not well understood by the Western man. In the West farming is the main business and the chief dependence of the towns. Money is invested freely in farm land. This gives farming a solid character as the leading industry. The price of land goes up, loans are easily made, and farmers become the leading class. In the East through several generations manufacturing or other city enterprises have become the leaders. They absorb money for investments and draw interest and humanity away from farming. Thus farm values have fallen, and boys and girls have left the farm. When the old folks grow old or pass away the farm is unoccupied or in the hands of tenants. The tide has now turned, however, and Eastern farming is rapidly "coming back" as a business enterprise. With better facilities for obtaining working capital the Eastern farmer will have better opportunities than ever before.

SOME weeks ago a reader wrote asking quite an important question. He did not sign his name, and the postmark on the letter was badly blurred. As a rule we pay no attention to unsigned letters. This question seemed to be a personal one, but there was no way of answering it by mail. Now comes another letter in the same writing again unsigned and without postoffice being named. This time the writer scolds because he has not seen his former question answered in print. The question carries no point that would interest the public, but we will answer it promptly as soon as this man complies with our fair and simple rule of giving his name and address. This is a small matter, but we want to make it clear that no one need have the slightest fear that we will ever betray his confidence.

*

OF late years we have had more and more people say that there is no more spirit on Fourth of July celebrations. The holiday does not mean what it once did. One must have a new idea of the meaning of "Independence" in order to celebrate the "Fourth." Here is a new one, for example:

Waupaca, Wis., voted out the saloons last Spring, and July 4 we had a great big community picnic for a "celebration"; city and country combine and have a social center programme.

That celebration meant something because it stood for a new independence—freedom from the legalized curse which has held thousands of homes in slavery. Freedom from the legalized saloon meant happiness the best that life has to offer to thousands of women and children. That gives a new spirit to the "glorious Fourth," and such a celebration reaches beyond its locality in its effect upon the temperance question. There must be a nation-wide sentiment in order to drive out the saloon.

*

I AM anxious to have you express your opinion of the average agricultural bulletin of the past, and to offer helpful criticism upon it. I would like to have you indicate what you regard as the ability of the average person for whom these bulletins are prepared. How technical and scientific may the material be? Is it necessary that technical and scientific information be expressed largely in technical and scientific terms or may such information be presented in common everyday language in these bulletins? F. W. B.

These questions are seriously asked by a teacher at an agricultural college. We have heard much destructive criticism concerning the station bulletin—its limitations and failures. The most common criticism of this sort is that the average bulletin "does not get anywhere." It states a collection of facts without making any particular application—usually in a dry, rather uninteresting form, out of reach of the "average farmer." Another criticism is that the bulletin is usually aimed at a scientist or a farmer of superior intelligence—not at the plain uneducated man who most needs such help as science can give him. This is the sort of criticism usually heard. Much of it is justified, but the station people have had a good answer. Their work has thus far been along the line of research, and it has not been their business to popularize the work. Granting that this has been so in the past, it may be the part of constructive criticism to suggest that the future should bring a change. We would like to see two kinds of bulletins issued—much like the plan followed by the two stations in New York State. There should be a scientific bulletin in which the author states his facts in scientific language without attempting to interest farmers. This should be for distribution among scientific workers. There should also be a popular bulletin on the same subject when the facts warranted it. Instead of having this written by any scientific worker we would have it prepared by some intelligent farmer who had made a success of the line of farming discussed in the bulletin. The object of this would be to obtain the language and the point of view of an actual farmer. Such a man would be far more likely to know how to interest other farmers than the station worker. This would be especially true of the younger scientists who have graduated from high school to college and laboratory without any actual life upon the farm. The National Department has issued several good pamphlets of this sort. Why not have the station go further? Suppose they discover some new fact about incubation, or cattle feeding or the use of fertilizers. We would have a scientific bulletin for scientific men. Then we would let some successful farmer, who had the gift of language, make a popular story out of these facts, for general distribution. This suggestion is based upon the fact, which we have long observed, that the teacher or the scientist becomes absorbed in his work, and usually forgets that "universal language" which one must have in order to appeal to the plain people.

AS to the 35-cent dollar, I believe the farmer will always be willing to take it so long as he operates individually and not collectively, and until he learns what it costs him to produce each and every article he manufactures upon his farm and operates only so much land as he is capable of making produce to its fullest capacity. One-half production with lack of buying and selling efficiency keep down the real producers, and the possession of these fundamental essentials enrich the manufactures whose foundation is the farmer's efforts at production. E. A. P.
New Hampshire.

The farmers are not willing to accept the 35-cent dollar, but under present conditions most of them are obliged to do so. Our friend is right in saying that co-operation and organization are necessary if we ever are to enlarge that dollar. Some farmers say they have no need of co-operation since they are situated so that they can sell direct to the consumer and thus get the full dollar. They forget, however, that they may be paying a 175-cent dollar for many of the things they buy, and that this eats up much of the profit on what they sell. True co-operation means advantageous buying as well as selling. The trouble is that under our modern business methods everyone wants to sell by the 175-cent dollar and buy with the 35-center. Thorough organization is the only way to adjust things fairly.

*

THE House of Representatives has passed what is known as the Clayton bill, and it is now before the Senate. This bill, among other things, exempts, from the provisions of the anti-trust measure:

Consumers, agricultural or horticultural organizations and authorized associations instituted for the purpose of mutual help, and not having capital stock or conducted for profit.

This has been heralded as a great victory or advantage for farmers, but a brief study of it will show how little there is to it. What sort of a position will farmers be in if in their attempts at organizing they are restricted to "mutual help" and denied the privilege of combining for business profit? There is no need of any such clause in the bill. If there is to be any exemption at all it should broaden the farmer's opportunities rather than restrict them. The present high cost of living cannot be cut down until the cost of distributing food is reduced. This can only be done by bringing producer and consumer closer together—an impossible thing except through organization. In such a service men will not organize for "mutual help" alone. There must be the inducement of fair profit. Yet this proposed measure would not permit such organization if there is to be any business profit in it. The law should go further than mere permission—it should encourage farmers to combine so as to purchase their farm supplies at a lower cost and sell their products at a fair price. In European countries farmer organizations are authorized by law and encouraged. Government aid and direction are given because all recognize the absolute necessity of keeping the farmer prosperous rather than giving other classes the opportunity to exploit or rob him. In this country practically every business is organized except the business of farming. There is combination everywhere except among farmers. Instead of restricting the operation of farm organization—as this law on its face does—it ought to be considered a national duty to broaden the scope of such co-operative work in every fair way.

BREVITIES.

THE "uplift" is one thing—true lifting up is quite another.

ALL is not gold that glitters, and all is not plant food that smells.

TRYING to chain a boy to a farm is usually a good way to break the chain.

IF fresh air through the day is voted right—then why, my neighbor, shut it out at night?

A MERRY heart goes many a mile and it is my belief that honest fun is the fungicide that kills the germs of grief.

EVEN the island of Ceylon offers a market for American apples. The trade is limited, but every corner of the earth should be reached to provide its share.

ON the whole it is wiser for most people to use their heads as a dictionary rather than an encyclopædia. You cannot hope to carry all knowledge—but know where to go after it.

BUBONIC plague has been found in New Orleans. This disease is carried by rats which are transported in vessels or in cars from city to city. All along the Atlantic coast rat killing is being organized.

IT is time to consider the Hessian fly in wheatfields this Fall. Burning over the stubble will help, but late seeding is the best remedy. Good judgment is required in this—to delay as long as is safe and still get the plants well started before Winter.

THE road mirror is the latest plan for preventing accidents at bad road corners, or dangerous turns. Many English towns have these mirrors in use, but the largest one is reported from Bombay. This is 10x5 feet, so arranged that travellers going either way may see what is coming around the corner.

WOMAN AND HOME

Making a High Scoring Milk

Steps Up the Scale

CARELESS METHODS.—Several years ago, in company with another young man, I spent a few days at a farmhouse back upon the hills many miles from a railroad. This farmer kept about a dozen cows.

READY FOR DINNER.

As it was late in the Fall, and the cows nearly dry, the local creamery was running only every other day. I helped milk the first night. The milk was strained into the can, and the can left standing in the cow stable all night, all the next day, and the following night. The second morning it was duly delivered to the creamery. For 10 years I have been wondering how that buttermaker could make "fancy creamery butter" out of milk cared for in that way. This may have been an extreme case, but one thing is certain—that is, more care and attention is being given to the production of good, clean milk than ever before.

PRIMARY REQUISITES.—A good many farmers have the idea that it is absolutely necessary to have expensive stables, concrete floors, metal stanchions, etc., before they can get a high score. Of course these things all help, but in the milk business, as well as in other lines, it is the little things that count. To prove this, and with the hope that this article will be of some benefit to some other young farmers who, like ourselves, have bought a farm and run heavily in debt, I will give some of our dairy experiences of the past six years.

THE MILK INSPECTOR.—A short time after we moved here, one afternoon I happened to look out of the window and saw a dudish young fellow come out of the cows' stable and drive rapidly away. I looked around, and not finding anything gone, thought no more about it until a week or so later, when I received a letter from the secretary of the Board of Health informing us that unless we put in a concrete floor and gave each cow so many square feet of light and cubic feet of air, etc., our milk would be rejected by the city. I promptly threw the letter into the stove, and declared we would get a separator and make butter. But the good wife, who is nothing if not diplomatic, and moreover does not like to make butter, wrote a nice letter, explaining that we had just bought the place, and could not afford to make the improvements mentioned just then, but hoped to be able to do so later. That was the last we ever heard from the secretary.

CURRYING COWS.—A few months later, one night, after I had been cleaning off the horses, the idea somehow got into my head that it might possibly be a good plan to clean off the cows. I had been brought up on a farm and had worked for a good many different farmers, but I don't think I ever saw a currycomb used on a cow before. The next morning the cows were all alive, and I really thought they gave a little more milk. I have tested it thoroughly since, and am sure that the time spent in cleaning off a good cow is time well employed, even if you care nothing about the improvement in looks.

SOME IMPROVEMENTS.—When we moved here the hogpen was along one side of the barnyard, only a few feet from the cow stable. The inspector always cut us a point on this account, so I told the boy he could have it for a henhouse, and he must look to them for all his spending money. A couple of new windows made a nice henhouse that would accommodate 30 or 40 hens. The boy made more out of those hens than I ever had out of pigs. This has nothing to do with the milk business, only it shoved our score up another notch.

MORE INSPECTORS.—The second inspector was from the State Agricultural Department, and claimed to have been a farmer. He gave us a couple of points on account of the cows being clean. He also said it was all right to use horse-manure in the drop as an absorbent, a thing some of the city inspectors had been kicking about. He also showed me how I could fix the drop so as to keep the cows cleaner, and left a score card. Then I began to think that possibly an inspector might be of some use in the world. The following Spring inspector No. 3 came along. He seemed possessed of one single idea, and that was whitewash. He said he would try to get the company to buy a big sprayer and loan it to the farmers. The company did that very thing afterward.

WHITEWASH.—I reasoned that lime was cheap, and so one rainy day I went at it. The stable had never seen a drop of whitewash. When I had gone over one side with a brush, I decided to work with a hoe and trowel first. I dug, scraped and brushed until I had worked such a transformation that when the cows came in at night they did not know where they were. But a brush goes rather slowly, especially overhead; you get it in the eyes, and when the last spot was covered I was very glad.

"WHITEWASHING."

SPRAYING WHITEWASH. — The following Spring the worms threatened to destroy some choice fruit trees. We decided to get a small sprayer to save them. It cost about $4, and was recommended to put on whitewash. Since then twice a year we take some lumps of stone lime, put them in an old tub, pour on boiling water, cover with a sack until it stops boiling, then add cold water until we get it thin and cool enough not to spoil the hose of the sprayer. It doesn't take very long to do the work, but it counted three points on our score card.

THE MILK-HOUSE.—For some time the company had been urging all its patrons to put up milk-houses. I will tell you what decided me to do so. A few years before there had been a State inspector around looking for watered milk. When a certain man drove up water was found in his milk, and he had to settle. Now, I had always believed this man to be honest, and do yet. I also knew that there were some people living in his vicinity who were none too good to take out milk and put in water. This man told me he did not mind paying the fine as much as he did the fact that if he lived to be 80 years old he would be sure to hear of the water deal any time some one got provoked with him. I didn't want anyone meddling with our milk. As soon as we could afford it I commenced drawing stone, gravel and cement for the foundation of a little milk house. After we had the floor finished, and before the frame was started, another inspector came along. He was a Board of Health man, and the sharpest and best up to this time. Whenever I think of him I think of a little joke he experienced when visiting a back farmer. After looking around in the cow stable, he asked the farmer when he had whitewashed the stable. The farmer replied, "Three or four months ago." The German inspector quickly said: "Vhy then you no vhitevash over my name I wrote here two years ago?" The farmer had nothing to say. The inspector asked me how I intended to build the milk-house. I told him where I was going to put a door opening into the wagon-house. "Now, my friend," he said, "don't do that." He showed me where that would cut off one point; also said get a wash-dish, towel, soap and dipper to put in the milk-house when completed. We did so and I have washed my hands many times when I would not have taken the time to go to the house. By exchanging work with another farmer, who is a better carpenter than I am, the milk-house was finished, and all it cost us was the cement, siding and ceiling-up lumber and roofing paper. After I had painted it, and the paint well dried, I was well pleased as I snapped the lock that at last our milk was safe.

STRAINING THE MILK.—About this time the manager of the station tried out a little scheme that was rather cute. There was a little steam-heated vessel. A pint of each patron's milk was put in and allowed to filter through a small pad of cotton. This pad was then put on a pasteboard under that patron's number. The cardboard was then hung up, so every one could see his own and his neighbor's pad. Those pads showed up every bit of sediment in the milk, and there were some very brown samples the first time. This test proved two things. One was that milk from some of the best-scoring stables was no cleaner than the milk from some who had no concrete floors, etc. The other was, that cheesecloth strainers were no good. The manager advised us to get outing flannel and put the fuzzy side up. After we had done so, the little cotton pads began to look better.

SANITARY MILK PAILS.—I think the next step we took up the percentage column was when the company sent out a few sanitary milk pails with eight-inch opening for the farmers to try. The company would furnish them at cost if the farmers would buy and use them. The two points which this would give us on score tempted me to get one. However, I cannot say I have yet got to the point where I can say I really enjoy using it, although it does keep a lot of dirt out of the milk.

FURTHER INSPECTION. — The company next tried the plan of hiring a couple of young fellows who were graduates of a veterinary college, who were to inspect stables and examine the cows at the same time. I never happened to be at home when the first one called, but the neighbors all spoke very highly of him, declaring that he seemed to be well qualified for his position and a nice fellow to get along with. He must be working in another section, as he has not been here r a couple of years. The other young fellow has been here several times. At first I never cared to see a milk inspector drive up to the barn; now I can truthfully say I enjoy their visits. This one especially, if he has time, will sit on a milk-stool and talk over anything pertaining to the milk business. He has helped us by suggestions that have been worth many dollars to us, as I will try to show later.

CHANGING CONDITIONS.—Up to this time I will admit it had never seemed to me to be of any particular use to take any extra care with our milk, as I knew it was all thrown together at the station. Of course I wanted our milk to be as good as the average, but did not think it did any good to have it much better. After a talk with the company's inspector, it began to dawn upon me that a new order of things was about due in the dairy business in our section. The company had recently purchased another station at our place. The inspector told us they proposed to make a model station and make two grades of milk. All dairies that scored 25 per cent. in equipment and 43 per cent. in methods would be taken in at the new station as soon as it could be completed, and would be paid a premium of 10 cents per hundred pounds. Then samples would be taken and sent away to determine the number of bacteria in the milk. If found to be less than sixty thousand per cubic centimeter another 10 cents per hundred premium would be received.

IMPROVING QUALITY.—We now had enough points on the barn score to get the premium. The inspector told us we would have no trouble in getting the other 10 cents on the bacteria count if we would take a damp cloth and wipe the cows' udders and flanks, and milk a little out of each teat in the drop at first each time we milked. He also advised us to leave the covers on the cans after they were washed and steamed at the station; then after straining the milk into them, the covers should be put on tight and the cans set in ice-water, and it would be better to shake the cans a little than to use a milk stirrer. This doctrine was contrary to our previous ideas about airing cans and tipping up the covers to let the animal heat escape. However, we were willing to try out his ideas, and our bacteria test has been all right so far.

EFFECT OF REGULATIONS.—How this plan of the company worked out can best be illustrated by the case of a man that we will call Brown. Brown had inherited a good farm, some money, together with rather an antiquated stable and methods. He was always having trouble with the inspectors, and did just enough to keep his milk from being rejected. When the first checks came after the new plan went into effect, Brown met one of his neighbors who had received both the extra premiums. Brown asked him how much his milk had brought him for that month. They compared statements. While they both had the same test, Brown's was 20 cents a hundred less than the other man's. Of course he had heard of the new plan, but had paid no attention to it. That night, after supper,

"SAT DOWN AND TALKED IT OVER."

Brown took his pencil and paper and began to figure. His figures looked something like this: He was making about 500 pounds of milk a day. Five times 20 cents would make just one dollar, or 30 dollars a month. He would just about average that for 10 months. This meant $300 extra over what he was getting for

(*Concluded on page 951.*)

Woman and Home

The Sexton.

Nigh to a grave that was newly made,
Leaned a sexton old on his earthworn spade;
His work was done, and he paused to wait
The funeral train at the open gate.
A relic of bygone days was he,
And his locks were white as the foamy sea;
And these words came from his lips so thin:
"I gather them in; I gather them, in.

"I gather them in, for man and boy,
Year after year of grief and joy,
I've builded the houses that lie around,
In every nook of this burial ground;
Mother and daughter, father and son,
Come to my solitude, one by one;
But come they strangers or come they kin—
I gather them in, I gather then in.

"Many are with me, but still I'm alone,
I'm king of the dead—and I make my throne
On a monument slab or marble cold;
And my sceptre of rule is the spade I hold!
Come they from cottage or come they from hall,
Mankind are my subjects all, all, all.
Let them loiter in pleasure or toilfully spin—
I gather them in, I gather them in.

"I gather them in, and their final rest
Is here, down here, in the earth's dark breast!"
And the sexton ceased, for the funeral train
Wound mutely o'er that solemn plain.
And I said to my heart, when time is told,
A mightier voice than the sexton's old
Will sound o'er the last trump's dreadful din—
"I gather them in, I gather them in."

—Park Benjamin.

THE domestic unrest of to-day is due not to changed ideals of womanhood but to the maladjustment of the mediæval home to modern conditions.

That is what we hear from Mary Pierce Van Zile, "Dean of Home Economics." She is right, but those who are used to shorter words would put it this way, "A fight for a full wood-box and a sink."

* * *

WE are trying to locate some of the little gasoline engines which are doing duty *inside the farmhouse*. We find a number that are doing housework—running washing machines, cleaners and half a dozen other hard jobs. There are thousands of such engines doing great service at the barn or outside on the farm, but just now we want more particularly the record of the "tireless hired girl," or the small household gas engine.

* * *

WE are often told that there are elderly people who can show 50 or more of their living descendants through several generations. It isn't often that a baby can figure the other way. A woman in Montclair, N. J., however, at 88 years old became a great-grandmother. The child which came in time to give this lady her title has two living grandfathers, and two grandmothers, two great-grandfathers and two great-grandmothers and the great-great-grandmother, eleven granduneles, eight grandaunts and three great-grandaunts.

* * *

IN the last magazine issue of Woman and Home, Mr. L. B. Crooker said that the cooks of certain sections were able to prepare special dishes as they could not be found elsewhere. There is much in this, and, following up the suggestion THE R. N.-Y. has obtained some remarkable interviews with noted cooks. An old-time New England housewife, a black mammy of slavery times, a pioneer on the Western prairie, and a domestic science graduate, will tell us of their star kitchen performance in their own words.

* * *

ALL sorts of new things are happening. The latest is a School of Mothercraft, started in New York. This school graduated three young women recently, one of whom, Miss Marion Taylor, said that she is engaged to be married and took this course as a preparation for matrimony. The school was really intended originally for would-be brides. We wonder what some of the grandmothers who were such wonderful housekeepers, and to whom we owe so much, would have thought of the plan of going to school and obtaining a diploma as a preparation for getting married.

* * *

THE Illinois Supreme Court has upheld the law granting suffrage to women. This law states that all women who are citizens of the United States, and have resided in Illinois one year, in the county 90 days, and the election district 30 days, shall be allowed to vote. A case was brought by a tax-payer in Cook County, who demanded that the election commissioners of Chicago be forbidden to incur expense for providing facilities for women to vote. The object of this was to test the constitutionality of the law. The Supreme Court dismissed this case. An appeal was taken to the Supreme Court, which now decides by a vote of four to three that the law must stand.

* * *

IF compulsory attendance at school is good for the youngsters, what about compulsory supervision of the school by the grown up? This is the way Prof. E. C. Elliott of Wisconsin puts it:

It should be said to parents—much of the efforts of schools and teachers is wasted because the school and the teachers do not understand your children; your principal school business is to see that the teachers do understand your children; it is your duty to understand what the school is trying to do for each child, in order that your home may be able to coöperate for the accomplishment of these same ends.

There is a good deal of talk about our public school system—both praise and blame. Too many of us talk without ever putting our face inside the local schoolhouse.

* * *

CONSUL JEWETT of Baden gives a table showing salaries paid teachers in Germany. Salaries have been advanced about 20 per cent. in recent years:

Years of service.	Men teachers.	Women teachers.
1 to 3	$404.60	$357.00
4 to 6	452.20	404.60
7 to 9	523.60	452.20
10 to 12	595.00	499.80
13 to 15	666.40	547.40
16 to 18	737.80	595.00
19 to 21	833.00	642.60
22 to 24	904.40	666.40
25 to 27	952.00	690.20
28 to 29	999.60	714.00
30 and after	1,047.20	714.00

Thus such salaries advance every three years—as they should. In many parts of this country the older teachers are put aside, the preference being given to younger women.

* * *

IN the last magazine number we printed several unusual requests which appealed to farmers or their wives. Within two weeks after this paper was printed we received nearly 70 letters from women who desired to enter a hen in the poultry contest, 50 letters from people who asked about that tenant farm owned by R. H., 22 from elderly people who wished to know more about the women who desired a home, and one from a man who said he was willing to take that prisoner as a hired hand. All these have been attended to. There is nothing quite like the way our people take hold of such things. We have often said that THE R. N.-Y. has more personal friends and confidants among its readers than any other paper in the country, and every time this is put to the test we have renewed evidence of the truth of the statement.

* * *

ONE of our readers wants to know if we believe the following from the American Medical Association:

Dr. Sims Wallace, late dental surgeon to the London Hospital, states that there are in this country about 21,000,000 teeth in a state of ruin through eating sweets, and urges the adoption of a diet containing farinaceous food in a form which will stimulate mastication, as brown bread, and also the eating of fresh fruit at the conclusion of a meal. By means of the fruit the teeth are cleansed. The best fruit for this purpose is probably the apple, which, if eaten at the end of a meal, leaves the mouth fresh and physiologically clean.

We try to believe every good thing said about apple eating and this one seems sensible. When it comes to figuring we are lost when we get much above 100,000 and counting teeth by the million is beyond us. The apple as a toothbrush, however, seems good. Some of the people who advertise dental preparations so freely might well take the hint and prove that their stuff comes closest to the ideal toothbrush—the apple. There is no doubt as to the value of coarse brown bread as a "chewer."

* * *

WE like the good old Saxon one-syllabled names. They are short and strong, and mean something plain and practical. As between a man named Montmoreney and another named Smith we should view the former with the greater suspicion until we knew him fully. It is a pleasure to know how THE R. N.-Y. has gathered about it an army of these sound and practical people whose name goes through life like a short, sharp sword. Out of curiosity we went through the New York list and found that in this one State alone we have the following number of readers:

Mr. Jones	179	Mr. Smith	713
Mr. Brown	334	Mr. White	151
Mr. Black	27	Mr. Grey	62
Mr. Green	149	Mr. Blue	4
Mr. Bacon	28	Mr. Ham	21
Mr. Frost	37	Mr. Waters	11
Mr. Steele	21	Mr. Gold	4
Mr. Silver	1	Mr. Irons	2
Mr. Short	17	Mr. Long	17
Mr. Quick	22	Mr. Down	3
Mr. Ketcham	10		

In our entire list there are about 2,500 Smiths and nearly 2,000 Browns—all, as you might expect, plain, substantial people—every one of them, like all the rest, willing to help THE R. N.-Y. family if it is within their power.

A Woman's Back Yard Garden.

POSSIBLY some of your village readers who have small unused patches of land that might be made into a nice garden do not know of the possibilities thereof, so I am going to tell them what I have on a little plot 27x65 feet. 250 strawberry plants; 55 hills of sweet corn; 48 celery plants; 39 tomato plants; 14 currant bushes; 10 hills rhubarb; 10 hills cucumbers; 6 hills cantaloupes; 5 gooseberry bushes; 2 horseradish plants; 2 rows beans 60 feet long; 2 rows peas 60 feet long; 4 rows beets 35 feet long; 3 rows lettuce 35 feet long; 1 row sweet peas 15 feet long. Everything is looking fine. All the room is fully utilized, yet there is plenty of room for all to grow, and produce well. The garden is the admiration of the neighbors. There are never any weeds in it. Fact is, there's no room to grow them.

Returns from Subscribers' Exchange.

THOSE four advertisements from farm women which were printed free last month all attracted attention and brought results. They have led to many sales already, and there will be many more. Here is a sample report from one of them:

From the little ad you inserted in Subscribers' Exchange, we have already taken orders for 10 dozen cans of Golden Bantam sweet corn at $1.75 per dozen, F. O. B. We received eight orders for sample cans. Will keep record and let you know just how many cans we sell from the advertisement.

MRS. W. A. SMITH.

We firmly believe that our readers are prepared to handle either end of any good bargain. Any useful article can be bought or sold if you can find the persons among our great family who need to buy or sell. This often requires time and patience, but so does anything that is worth while. Advertising is like seed sowing. It requires long and patient care to get full results.

* * *

The Most Important Thing.

WHAT do I think the farm women of my neighborhood need most? There are two things I would mention first, and I hardly know which I consider the more important. I think I will place first the matter of money. On many farms there is very little to use for anything except the necessities of life, and the man of the family usually has the spending of it. Now, there is no woman, whether she lives on the farm or in the city, who does not like to have some money to spend as she likes, without any questions asked. I am not speaking of any given amount, that is a small matter, but if she were allowed only $1 a month to do entirely as she liked with she would get more pleasure in spending it than with five dollars that she had to *beg* for or even *ask* for. If she had a chance to earn something in what little spare time there is on the farm, I believe it would give many a woman a new interest in life. If there is nothing for her to do to *earn* it, I believe every man ought to enter married life with the idea that his wife is his partner as well as his helpmate and that she should be given *some share* of the money that comes in for her own benefit, to use as she sees fit. Many times the woman has the better business head, and the money given her would go much further than in her husband's hands. She might spend it for the same things as he would, but she should have the privilege of saying how it should be spent.

MRS. S. C. DAMON.

Your Home to Yourself.

SINCE we sisters were babies and mother was ill we have never had a maid staying in the house. There has been a procession of women and girls coming in by the day or hour to do the harder work, and some of the girls we have trained have been among our warmest friends. During the past week we have had an elderly woman here for a week on trial. She is honest, neat and willing, but preternaturally slow, and likes to talk of her defunct relatives. Finding this annoyed me, she has made a brave attempt to stop, but has evidently lost her only pleasure in life. Father and I are agreed that we prefer having our house to ourselves. I have heard a good many say the same thing, but never had it come home to me so strongly before. At present the house doesn't seem really like ours. It is strange that an alien presence should so disturb the home atmosphere. I shall be so glad to go back to my cheerful young helper, who comes in on the rush, chatters about her girlish happenings and brings any bits of local news, does her work and sits with me a while if we both happen to feel like it. We hereby join the procession of people who prefer to get along anyhow if they can keep their homes to themselves. Beside the annoyance of a stranger's presence, there is the expense of food, more expense for fuel and more waste and the wages to consider. We have learned a lot from our week's experience.

THE LAME HOUSEKEEPER.

* * *

The Miserable Cockroach.

ONE of the meanest house insects is the cockroach. It is mean because it multiplies so rapidly, and can run about so actively. It is impossible to keep food of any kind from being devoured, unless closely covered. These insects not only eat leather and parchment, but linen and paper. They are night workers, and even bite people in their beds, especially children whose fingers are left greasy. During the Winter they lie torpid, but in Spring they rush out to their mischief. The Agricultural Department advises the use of traps. You mix one part of plaster of paris with three or four parts of flour. Put this dry mixture in a saucer on a flat piece of wood, where these roaches are numerous. Nearby put another flat plate containing pure water. Make it easy for the roaches to get to the water by putting small pieces of wood or cardboard where they can crawl to the edge of the plate, and float one or two different pieces of wood on the water, so they will touch the edge. The insects eat the plaster mixture to get the flour. They then become thirsty and drink. The water makes the plaster of paris set inside of them and kills the roach. Another trap has for its bait stale beer, of which it is said these roaches are very found. This stuff is put into a deep dish or jar. Flat pieces of rough wood are placed on an incline against the vessel, and bent over into it. The roaches climb up these sticks to get the beer, and slip off down into it. There are various other traps, made on the principle of inducing the roaches to get after some form of bait and fall down into a box so that they cannot get out. A liberal use of insect powder will destroy many of these insects, but not all. It is not a perfect insecticide, but the traps spoken of above are said to be far more effective.

Making a High Scoring Milk

(*Concluded from page 949.*)

the year. It would cost no more to feed the cows or any more men to milk them. Three hundred dollars was 10 per cent. interest on $3,000. That was better interest than he was getting on his money in the local bank. Before he went to sleep he resolved to go and see a couple of modern stables, and before night he had a good carpenter drawing plans for a new stable. About the time the stable was completed the inspector came around, and for the first time in his life Brown was anxious to see him.

"Hello! Put out your horse and stay for dinner," were his first words. The inspector, who had been there before, nearly fell out of the wagon. That 20 per cent. premium had done the business.

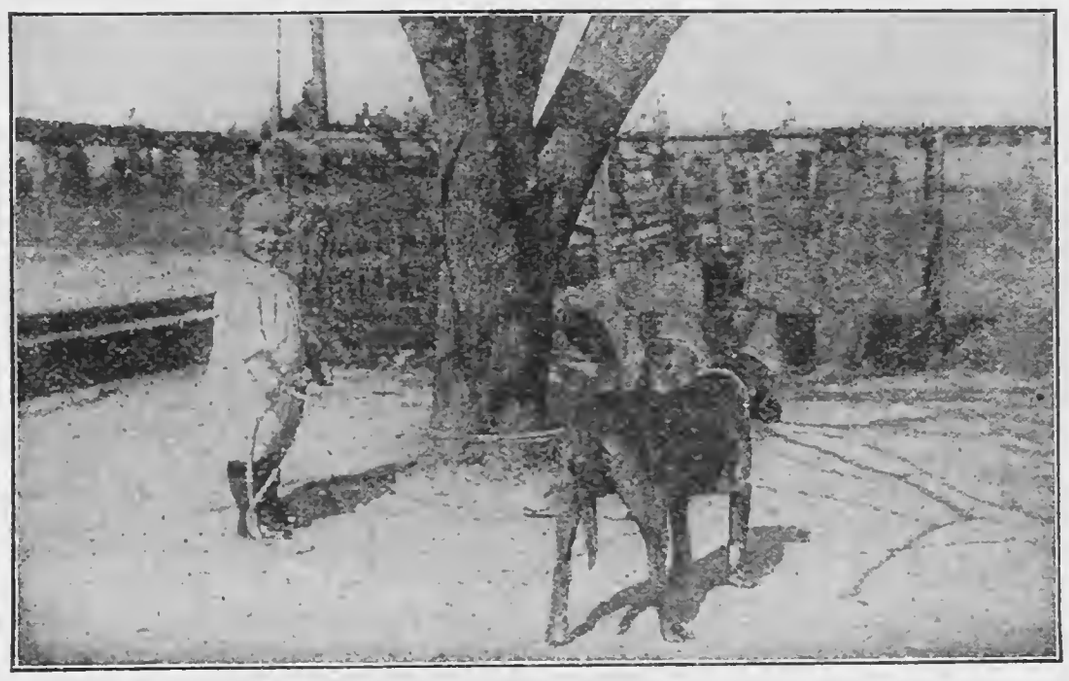
The last bait the company has thrown out is a 10 per cent. per hundred premium each month if the milk is cooled down to 50 degrees each day when delivered to the station. This went into effect April 1, 1914, and most of the farmers in this vicinity have laid in an extra supply of ice, hoping to succeed in getting that premium, too.

RETURNS FOR CARE.—Occasionally I hear some farmers long for the good days when milk was bought without regard to test, and inspectors were never seen. Now I, for one, am not at all anxious to go back to the old ways. I will tell you why. About 20 years ago, one Summer my father drew his milk to the nearest station for the large sum of 44 cents for a 40-quart can, a little less than 52 cents per hundred pounds. This I know to be a fact. During the present month (April) our milk is testing 5.3 per cent. or eight points above the standard. We receive four cents a point, or 32 cents premium on test. Then if we get 10 per cent. for cooling, and adding the 10 per cent. bacteria test, 10 per cent. barn score makes a total of 62 per cent. in premiums; that is 10 per cent. more than the first price my father received for his milk. As to the future of the milk business, I wish I could see 10 years ahead. It seems as if there would be an increasing demand for good milk, especially in July and August. Physicians have found that the acid in sour milk is very beneficial in certain diseases. We all know that good buttermilk is one of the most healthful drinks known. How much better in every way it would be if the millions that are spent each year for beer, wine and whisky could be spent for good milk, buttermilk and grape juice! If I can read the signs correctly that day is on the way. J. C. G.

Let Drunkeness "Cures" Alone.

MY friend came to me yesterday; she had read an advertisement about ———. Her husband has become a drinking man, and now that he is only working on half time, work being dull, he is drinking worse than ever. He is a nice man, but for this one thing. He has one child. Drink seems to make him extremely cross. The home is being ruined by his drinking. His wife is a nice woman, very intelligent. She read that ——— would cure the desire for drink. Will this stuff cure or even help this drinking habit; are these testimonials true? And secondly, will this treatment in any way injure the person to whom it is given, mentally or in any way? She would have to give him the treatment unknown to himself as he would not take it if he knew. MRS. S. P. S.

Among the most heartless of the cruel frauds perpetrated by medical quacks are those which appeal to the love of a mother or wife for one who has become a drunkard. This love and the helpless misery oftimes accompanying it are traded upon by those who advertise secret remedies for the drink habit, and the very fact of the necessity for secrecy is depended upon to save them from exposure at the hands of their dupes. As a type of these secret cures, the one named is one of the most widely-advertised. It has been investigated by the American Medical Association and its fraudulent nature exposed. In the advertisements of the concern behind this "cure" you are asked to write to a Mrs. Margaret Anderson, who professes to have cured husband, brother and several neighbors by a simple remedy which she is anxious to tell others of. If you write, you receive a letter in well imitated handwriting, assuring you of her heartfelt interest in you and telling you that she has asked the Physicians' Co-operative Association of Chicago to send you a trial treatment of the remedy that has worked such wonders in her own hands. Of course, you promptly receive this trial treatment, which consists of a number of variously colored tablets which you are to administer to the unfortunate victim of alcohol. You are also urged to send for a complete treatment, and if you do not respond promptly, you are bombarded by "follow up" letters in which the price of the treatment is gradually reduced with the hope of at least getting something out of you. An analysis of some of these tablets in the laboratory of the American Medical Association showed that their most active and dangerous constituents were strychnine and tartar emetic, drugs which, it is hardly necessary to say, could not possibly cure alcoholism, and which in the hands of the ignorant or careless are dangerous poisons. Until the time comes when all reputable journals refuse medical advertising, as the more conscientious among



"YOU GOTTA STOP KNOCKIN' MY DOG AROUND."

them already do, the miseries of humanity will furnish a field for exploitation by quacks, and among all their victims few, perhaps, are more to be pitied than the wretched sufferers from the drink and drug habits. M. B. D.

Meals Without Cooking.

IN the matter of getting meals, we have grown into an artificial way of life, which entails untold work on the women. Especially is this hard on the farm woman. Our horses and cows get the same feeds year in and year out, and they continue healthy and able to perform duties required of them. Horses have mainly oats and hay and water. Cows have bran, silage, grass and hay (sometimes only water and straw). These things for animals are supposed to furnish a balanced ration. We can have an equally well-balanced ration just as simply, but age old custom has decreed that we should put on a good deal of "fuss and feathers" in preparing "tempting" dishes. You don't have to "tempt" the appetite of a hungry, healthy man.

For myself, I can go out in the yard or garden and dig out large stones, spade, and do other heavy work without breakfast, and at 10 oclock, come in and eat two shredded wheat biscuits and apple sauce and cheese, and be satisfied until the next meal, at four o'clock, which may consist of another dish of apple sauce and some cold corn bread, with sour milk, or sweet milk, or buttermilk. On this diet, I can work hard, day after day, and at the same time, practice music and write.

But you will say, "How about your men folks? They, we imagine, would hardly be satisfied with a hunk of cold corn bread and some sour milk. Hogs might, but not men." Well, our man (that is, the head of our family), who is one of the strongest men in the neighborhood, as shown by his being able to outdo most of the others in muscular feats—our man eats for breakfast, two shredded wheat biscuits, some cheese, apple sauce and cream, and that is all. When I thought of writing this article, I asked him what kind of a meal he would like, if he had just what he wanted.

"One thing," he replied, "either peas, cooked with cream and bread and butter, or sweet corn, on the cob, or canned, with bread and butter, or cream tomato soup and bread and butter."

"Wouldn't you like anything more than that?" I asked.

"No, not if there was enough of it," he replied. So you see the man of the house wants something hot. Bnt you can also see that it ought not to be a very heavy burden to provide meals for him. And he gets up at five and works hard all day, and sometimes into the evening. I often have a lot of potato salad ready and if he has that at night, with bread and butter and an egg or two, he is more than satisfied. So all the trouble about his supper is to boil him two eggs.

I have stopped cooking for hired men. My life was frittered away over the cookstove for men, often rough, and often critical, who demanded more in the way of pies and cakes than we should ever care for, and for whom there always had to be a lot of fussing and cooking, which is almost entirely eliminated when we are alone. Life has become a different matter to me since this tri-daily recurring burden has been lifted from me. And we are never sick, not a day, and we were, before.

We have all kinds of vegetables and all kinds of fruits and melons. We use a great deal of fruit, also can it, and vegetables, having a steam canning outfit. We also can pork and beans in our steam outfit, and they are said to be equal to those which advertising has made so famous. Generally there is some one here, so we cannot always observe this primitive simplicity of diet, but we do when we can, and in Winter have only two meals a day. As the breakfast is always the same, and requires no cooking we have very little work. We simply shove a piece of ham or fresh pork, or sausage into the sitting-room stove, on the coals and warm up a few potatoes in the same place, and presto, all is ready! We now have a fine fireless cooker, so the work can be still more simplified.

ELLEN E. DE GRAFF.

Removing Surplus Hair.

WILL you inform me how to kill hair that is not needed? The hair on my neck is as thick as on my head. I want to remove the hair so it will not come back. S. A. R.

All sorts of questions come here. At about the time this question came we had a visit from a bald-headed man who was grieved because there was no hair growing on the top of his head. This man was grieved because certain ladies of his acquaintance seemed to dislike the appearance of his head. Another young man was grieved because he seems unable to grow a beard, and yet here comes one who wishes to get rid of surplus growth of hair. It is said that people with too much hair or those who have too little or those with the wrong color help to support an army of doctors. There are two classes of depilatories. Some of them are chemicals which remove the hair but do not destroy the roots. Many of these are sold under high-sounding names, and fortunes are made by the manufacturer, but the hair grows again. The effective treatment for killing out hair is the use of the electric needle. This is slow and painful, each separate hair root being treated by itself. The roots of the hair are destroyed and it will not grow again. Many people actually use a clipping machine or razor daily to keep such hair in check. The electric treatment appears to be the only really effective method.

Grease Trap in Septic Tank.

I AM planning to put in a septic tank, and in Circular 34 of the Wisconsin Experiment Station, find it stated that a grease trap is an essential part of a satisfactory system, giving instructions for its construction. For the body of the trap they use two 24-inch glazed sewer tile costing $2.50, but I find that here they would cost about $12. Is it necessary to have a glazed surface? I could make it much cheaper of cement. My fall is limited, so it will be necessary to build the tank as high as possible. There is no cellar under the kitchen, only a space about two feet high. Would it be safe (on account of sewer gas) to build this trap under the kitchen with the tank located outside the wall?

Brookfield, Mass. J. W. S.

As the principle upon which a grease trap operates is simply the providing of an accessible chamber in which the grease may rise to the surface of its contents and be removed before entering the septic tank, it may be built of any water-tight material. Except in connection with a dairy room or some other place where a very large amount of grease is discharged into the sewer they are not, I believe, often installed. As the type of grease trap you mention is in itself a trap for the sewer gas from the septic tank, I see no reason why one could not be safely placed under a kitchen floor.

M. B. D.

Poison Ivy Notes.

AS to goats eating poison ivy, I put my flock of Angoras in a field in which there was a log cabin which was about half covered with it. They ate it as high as they could stand on their hind feet and reach. I cut the big main stems through with ax and they kept the suckers eaten off till all was dead. It did not harm the Angoras, but there were so many they did not have much of it to eat. With two or three goats in a large patch of it, it might turn out differently, but anyway Angoras will eat it.

Arkansas. C. E. DEGROFF.

I HAVE an old place completely overrun with poison ivy, and when we get rid of it in one place it crops up in another. My doctor gave me the following remedy that is so simple and has proven so efficient in cases of ivy poisoning that I am glad to add it to your list. Add enough quinine to vaseline or lard to make a thick salve and apply to affected skin. Even in severe poisoning the curative effect is seen after a very few applications. MRS. DONALD WILSON.

North Carolina.

Canning Ear Corn.

MOST housewives are familiar with the process of canning sweet corn when cut off the cob. Of late years there has come a demand for corn preserved on the cob. The Department of Agriculture gives the following directions for preparing it:

"Blanch in boiling water five to 10 minutes, according to ripeness, size and freshness; plunge quickly in cold water. Pack, alternating butts and tips; add just a little boiling water and one level teaspoonful of salt to each quart. Place rubber and top and partially tighten. (Cap and tip tins.) Process 180 to 240 minutes in hot-water bath; 1½ hours water-seal outfit; 60 minutes under five or more pounds of steam; 40 minutes in aluminum pressure cooker. Remove jars, tighten covers, invert, and cool. Heat up for table use in steamer, not in water. If corn seems flat or water-logged, it has been over-cooked or allowed to stand in too much water. Use one or two-quart glass jars if not needed for other products. Quart jars will hold two ears, two-quart jars will hold from three to five ears, according to size of ear. Do not can large ears. Half-gallon or gallon tin cans with large openings should be used in the canning of ear corn when idle glass jars are not available. Gallon tin cans will hold from six to 12 ears. They should be graded to uniform size.

"One advantage of sweet corn canned on the cob over other canned corn, is that all the best food values are kept with the cob. In cutting corn off, the germ quality of the kernel, which keeps up its standard, is usually lost. This germ quality is the part of the corn that is sought by rats and mice when they look for food in the corn bin, and is the most vital part. Much of the corn is also rendered mushy when it is cut from the cob."

∴ A Woman Hay Farmer ∴

How She Handled the Crop

THE LAND.—When a lovely old mansion came to the family with 12 acres of intervale grass land attached, it seemed natural that I, who loved all outdoors, should be chosen to "run the farm," not with the expectation of making money, but with the modest hope of keeping the land in good condition and making it pay for itself. I went at it on a business basis. The land was valued at $1,000, so $72 was considered a fair rent, being approximately 7 per cent. on the money invested. I, as one of the joint owners, receive a third of this rent. "Ask everyone's advice," said an experienced member of the family, "and then do as you please." This valuable suggestion should be written in letters of gold, for out of it has come all my nuggets of wisdom gathered in three years' experience. The farming world is very kind, and will spend any amount of time, standing first on one foot, then on the other, giving neighborly information as to seeding down, rotary crops, and sweetening the land.

EARLY EXPERIENCE.—The first year, 1909, the haying was done by the job, at a cost of $45, and this, plus $72, was the whole outlay. The crop was light, for the land was rather "run out" in spots. I sold my hay for $146 in a lump. A pasturage of cows after haying brought $16 more. $146 plus $16 equals $162, income; $72 plus $45 equals $117, expense; $162 minus $117 equals $45, net profit. In 1910 four acres were seeded at an expense of $101.44; also two acres of sweet corn were planted at a cost of $109.12. The hay was sold for $110 "stumpage," and the corn brought $80 to the acre, being a little light owing to a raid of woodchucks. The year's work stood me as follows:

Hay sold	$110.00
Corn	160.00
Fodder plowed in	10.00
Total income	$280.00
Cost of seeding	$101.44
Planting corn and hauling same	109.12
Rent	72.00
Total expense	$282.56
	280.00
	$2.56

From a purely financial standpoint this result left much to be desired, but I knew my land was in much better condition, and the woodchucks looked so plump and

HANDLING THE SWEET CORN.

appreciative. 1911 was the banner year of my farming experience. I seeded down two acres. My hay was of excellent quality, perfectly cured, not a drop of rain coming upon it. With 24 tons crammed into my barn I felt at peace with all the world, and started for Boston in search of culture.

FINDING A MARKET.—One day, walking up Boylston street, this peace was disturbed by a male relative. (Male relatives are so plain-spoken.) "Have you sold your hay?" he demanded. "Why, no," said I, "not yet." "Not yet! What are you dreaming about? I should think it was up to you to get awake. I know of some one who has just sold a hundred tons for $27 a ton. Here it is the last of May. The thing for you to do is to find a market, then go home and press your hay and ship it before the new crop is ready." As he left me I actually panted with excitement. "Find a market" seemed as preposterous as to hunt for a pole, and the only pressing I knew anything about was the pressing of my clothes. But a remembrance flashed through my mind of a transaction highly cherished by my family, probably because it was the first occasion that I showed any business ability. This transaction was the sale in two hours, in a small village, of a hundred cords of wood. I nerved myself to sustain my reputation. The next hour was spent in inquiries concerning hay men in general and honest ones in particular, after which I boarded a Cambridge car and began my interviews with a calm face and wildly thumping heart. I learned that if the market could have just what it wanted, it would be Herd's-grass of a coarse quality, with a sprinkling of clover and Red-top, pressed in 200-pound bales, and, in order to get a good price, it must be shipped during the next three weeks.

ALL HANDS IN THE HAYFIELD.

PRESSING THE HAY.—Two days later found me at home telephoning hither and yon for a hay-press. The only thing available was one of the old-fashioned sort of two-horse power, and this seven miles away. It required six horses to bring it, and a proud day it was when this imposing chariot appeared and was set up in the barn, to be mine until honorably discharged. We started off in high feather, my four men and two horses. The first bale was turned out "in the shake of no time." The second, a little more slowly with discouraging creaks. The third bale groaned dismally and ended in a savage bang, which said as plain as day that something had broken. It was the big iron shaft. My men said there was a flaw, and they never saw such rotten iron. The blacksmith said there was no flaw at all. The owner said it was a "brand-new shaft," and I must pay for the mending. My men and horses went home. Fearing the shaft could not be mended, I telephoned for a new one, with the understanding that I should bear one-half of the expense. This came straggling along after four days. But in the meantime the old shaft was patched up, and with much telephoning and bicycle riding my industrial army was again assembled, and we started, fearful of the worst. But the expected did not happen, and we dragged on, taking six days for what should have been done in three. During these six days I learned a number of things, the most important of which was, that even I, the inexperienced presser of the hay, could help materially by being on the spot.

GETTING IT SHIPPED.—With the help of my wheel I made breakneck rides in all directions. There were cars to engage, bills of lading to understand, and a hundred and one unexpected happenings to settle. "He who would be well served must serve himself"; so it was the owner's eye that discovered the unswept cars and the careless packing of bales. A broom and shovel soon made the one right. The first layer of bales I turned on their broad sides, the others on their narrow sides, thus squeezing an extra bale in each tier, and filling the extra height in the car, which made a big difference in my profits, as a loosely packed car costs as much to transport as one filled to the limit. My cup of joy was full when I learned I was three tons better to the car than one of the, presumably, experienced "men folks" who shipped alongside of me. By dint of rushing, employing extra men and horses in its transportation, we just made connections. As the freight train steamed into the station and side-tracked itself to take on freight, the last bale was put in and the door locked. It reached its destination in time. My bales satisfied the buyer, and the trials of hay-pressing were forgotten in the gratification of receiving a substantial check.

RESULTS OF 1911.

EXPENSE.

Seeding 2 acres	$79.00
Haying	68.00
Rent of press	12.00
Transportation of same	12.00
Pressing 24 tons	88.22
Half new shaft	5.00
Mending old shaft	2.50
Telephoning, etc.	2.00
Two cars for transportation	50.00
Rent of land	72.00
Total expense	$390.72

INCOME.

24 tons of hay at $27	$644.96
Second crop	8.00
Total income	$652.96
	390.72
Net profit	$262.24

While I have been obliged to hire all labor done, I have looked after the essentials needed, ashes, manure, phosphates, etc. I have hired my men, paid my bills and fought my own battles, notwithstanding that I was much of the time actively employed in a distant city. The figures of this banner year show that financially I came out with flying colors; but more valuable even than the money made has been the experience in business and with human nature. But the most satisfying thing of all is my well-tilled land, stretching off towards the mountains, the tall, waving grass, the bees and butterflies that take toll from my clover-heads, and the swinging, gurgling bobolinks, to whom my little farm is a "joy forever."

Maine. HATTIE A. PIKE.

Homemade Cheese Making.

TWO months ago Mr. Clark Allis gave his wife great praise as a cook and housekeeper, mentioning particularly a certain kind of cheese. There have been several requests from readers for further information about this cheese, and so we are able to print the following:

I am sorry my husband has got me into trouble about cheese-making, for I have never seen a professional cheese-maker make cheese, and only know what I have learned from articles in agricultural papers and some hints which a Scotch woman gave me.

Get from a butcher a calf's rennet, fill and cover with salt, using plenty—a pint or more. Dry thoroughly and roll up in clean brown paper. When ready to make cheese cut from your rennet in half-inch slices about two inches; put into a pint glass can and fill two-thirds full of hot water, using the salt, and adding more salt if in keeping it shows signs of mold. Let stand over night. When the liquid has been used add more rennet and hot water. It will keep for months.

I have only tried making cheese from small quantities of milk in the Winter. Then I would save my skim-milk till I had about three gallons and a half. Heat the milk to 85 degrees, add one tablespoonful and a half of the liquid rennet and let it remain till solid, like thick, sour milk, usually about half an hour, sometimes longer. Cut the curd in squares with a long knife or spoon, and when the whey begins to separate carefully dip off with a saucer or shallow skimmer. Heat it to 90 degrees, pour over the curd until the whole mass is heated to 90 degrees, when the curd will settle in a mass to the bottom and all the whey can be turned off. We like this fresh curd, and eat it with salt or salt and cream. Make curd in this way three times, keeping it in a cool place, but not allowing it to freeze. The last time I put all the curd through the food chopper and salt to taste.

Mr. Allis had made a tin hoop nine inches in diameter and six inches high, with a row of small holes on one side to let the whey escape; two tin heavy galvanized iron circles and several wooden ones one inch thick, which fit loosely inside of the hoop. The galvanized iron circular pieces should be just as big as possible and go into the cheese hoop. The wooden ones can be a little smaller.

Place hoop on a board and take a cloth about the size of a flour sack and place inside of hoop. Put in one of the tin circles, which fits it to the hoop. Now fill in the curd and even it around, draw a corner of the cloth smoothly over the top and place on the other tin circle. Draw up all the loose edges of the cloth on top and put on as many wooden circles as you need. The cheese is now ready to press, and you can press it by placing a big stone on top, or in whatever kind of a press you can improvise.

When I make cheese of the whole milk I save the night's milk, and in the morning take off the thick cream, which would waste, and with the morning's milk make it into curd. If I want a larger cheese I keep the curd on ice till I have enough to press. The morning after I take the cheese from the hoop, remove cloth and rub all over with melted butter, and it is then ready to use as we like it. If you

A PAIR OF ALABAMA BOYS.

want to cure it longer, turn it every morning, rubbing it all over with butter as you need it. MRS. CLARK ALLIS.

NOTE.—Mrs. Allis has a heavy plank press, two planks, with a rod through each end, threaded nearly its length, and two big tail nuts to turn by hand; but I think a lever press with a weight at the end might be an improvement. Any kind of a press that will go down square and not make the cheese one-sided is best. The common lever apple presses might be used by hanging a weight on the lever.—C. A.

MRS. HIRAM OFFEN: "Your recommendations are rather poor, I must say." Maid: "Well, umm, yez weren't recommended very highly to me, ayther."—Boston Transcript.

The Summer Boarder

One of Them Talks

Suggestions By a Guest

FIRST REQUISITES.—On the comfort of the Summer boarder under your roof depends his return another year, and the only satisfactory way to carry on the business is to have the same people year after year. The standard of living everywhere has improved, and people ask more than they used to, but on the other hand they are willing to pay better prices than they did a few years ago. A houseful of boarders in the busiest season of the year involves a lot of hard work, but the material rewards are very considerable, and unlike many other ways of earning money, all the effort is on familiar lines. Three things are essential, good and abundant food, a clean and comfortable house and considerate treatment. And few country places have such advantages of scenery, tonic atmosphere, or facilities for amusement that people will overlook the lack of any one of these essentials.

THE TABLE.—The table in many country boarding houses suffers from the ambition of the hostess. People do not expect the variety of a restaurant, or even of a large city boarding house. In their own houses, well-to-do city people live simply, but everything served is the best of its kind. Such people, and they are the sort whom you wish to attract, will never miss layer cakes and pies from your menu, and they are satisfied with a breakfast of eggs and fruit. But they do expect good coffee, cream and butter that is above reproach. If the economic conditions of your house are such that every egg and every quart of milk has a marketable value, do not take boarders, but look about for some other way to earn money. If you do make the venture, impress upon your soul the fact that generosity pays, "is profitable for the life that now is." For breakfast, which need not vary from day to day, have fruit, a choice of cooked or uncooked cereal, either muffins or toast, and be prepared to cook eggs for each person as they are wanted. Have your fruit chilled, your coffee poured off from the grounds and kept boiling hot, and make up your mind to the necessity of plenty of cream for the coffee, and if not cream at least rich milk for the cereal.

CATERING SUGGESTIONS.—It is often difficult to get good meat in the country, but the larger cuts are sure to be better than steak. If you have six boarders, you should be able to have a roast three times a week, one dinner of lamb chops, cut thick and broiled, another of corned beef or ham, fish on Friday and chickens on Sunday. Let two of the roasts be beef, the other lamb, or have one each of beef, lamb and veal, but avoid pork as you would sin. A boiled dinner of a big piece of lean beef, with the vegetables cooked by themselves, is liked by a great many people, who would not touch it if meat and vegetables were cooked together. If you find any one person has a prejudice against it, it is easy to provide something else for him. Roast veal should also have an alternative. You cannot have fresh vegetables in too great quantity, two sorts besides potatoes are enough for one dinner, with perhaps cucumbers or raw tomatoes. Better save salads for supper. The saving of time in a Summer of baking the potatoes for dinner is very considerable. For dessert ring the changes on half a dozen cold puddings, apple pudding, bread pudding with fruit and fruit shortcakes. If possible have fresh fruit on the table, and a cup of tea should always be available with the dessert.

DINNER AND SUPPER.—With the dinners, variety from day to day is an important point. If you have roast beef on Monday one week carry it over till Wednesday the next, and have different vegetables with it. Do not give your boarders an opportunity to know what they are going to have for dinner before they enter the dining room. One reason living at restaurants is so popular is that people get tired of the deadly monotony of home and boarding house tables. Suppers should be dainty, but also substantial. Sliced cold meat, or simple hot dishes, meat heated in a brown sauce, creamed fish, spaghetti with cheese, or bacon and eggs, should be accompanied by some sort of a salad, fried or creamed potatoes. Warm bread is by no means essential, but always provide two kinds, brown, whole wheat or graham, as well as white. Add berries or stewed fruit, fresh, plain cake, or hot gingerbread, with the choice of tea, cocoa, or milk, and your guests will have nothing to complain of.

SERVING THE MEALS.—As to the hours at which meals are served, something depends upon the habits of your guests. Eight is a safe hour for breakfast and one for dinner. The six o'clock supper, which is the rule in country places, is often felt to be a great inconvenience by guests off for long walks or drives, or intent on enjoying daylight as long as possible. Seven o'clock in the early part of the Summer and half past six after the middle of August will be acceptable to most people. The goodness of the table depends very much on the goodness of the supplies. It pays in every way to buy groceries in the city, in sufficiently large quantities to secure free delivery, at least things like coffee, tea, cocoa and cereals. Lay in, also, a good brand of olive oil, in gallon cans, whether your own family uses it or not, and always have it on the table at dinner and supper.

COMFORTS AND CONVENIENCES.—In the matter of comfort, no one item counts for more than the thorough screening of the house. If you cannot afford movable screens, tack wire netting over the outside of the window frames, their entire length. Black mosquito netting, plain, not cross-barred, will answer perfectly well for the upper floors. Indeed this arrangement is much better for the bedrooms, as it enables people to have their windows lowered from the top, and guests are often irresponsible about screens. And the very first thing to do in the morning is to throw open all the windows on the lower floor, even if they must be closed later. Little conveniences in the bedrooms, abundant hooks for clothing, upholstered boxes under the windows in which all sorts of odds and ends can be tucked away, a shelf covered with gray blotting paper and bracketed below a window for writing, weights to hold doors open and wedges to tighten rattling windows, are trifles in themselves, and cost little, but mean much to guests.

BATHING AND LIGHTING.—The average country house has no bathroom, and some arrangement must be made for a supply of hot water, night and morning. This can be done by having a round tin wash boiler of the largest size, fitted with a cover, standing upon a single burner oil stove. On a shelf above it keep a row of the three-quart stoneware jugs sold for 10 cents each, one for each boarder. Light the stove an hour before bedtime and the first thing in the morning and there will be an ample supply for everyone. Another difficulty is lighting the bedrooms. Provide for this purpose the sort of lamp which is set inside a cylinder of tin, with a handle at the side. These are admirable for the people who want to read in bed, and are not expensive.

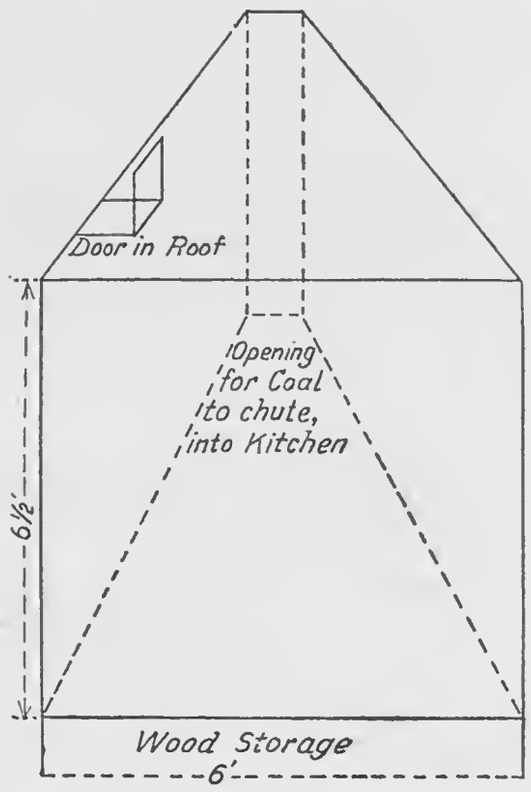
BUSINESS MANAGEMENT.—Consideration involves a good many things which are perfectly obvious, like charging a fair price and living up to all one's agreements. Something less obvious is an air of cheerful serenity on the part of the hostess. A willingness to go beyond the strict letter of the law is always appreciated. Meeting your guests on their arrival and getting them to the house as quickly as possible creates a favorable impression which is an auspicious beginning. People who have wandered around a strange town at twilight, hunting for a conveyance, and have reached their destination only in time to sit down to a cold and belated supper, are quite likely not to return. The old family ideal of the boarding house has disappeared. The more nearly impersonal you make your relations with your guests, the more likely you are to succeed. It is best to have the meals of your own family at a different hour, and to ask one of the guests to preside at their table. Above all things do not allow your children to inflict themselves upon your inmates. For one who enjoys juvenile society half a dozen will be bored by it. The question involved is not a social one. You and yours may be the equals of your boarders in education, in culture, in refinement, but it is no more material to them than it is to me to know that the clerk of whom I buy four yards of blue charmeuse shares my interest in old china. Our relation is purely a business one, and it is yours with your guest.

ELEANOR ALISON CUMMINS.

The City Boarder Saves Labor

"MRS. WARE," remarked the city boarder casually, "why do you keep the coal in the cellar?"

Of course, it was a direct, pertinent question and Mrs. Ware eyed the young man intently. "Where else could I store it?" she returned. Her manner was confusing, but not to a young man with a purpose in view.



LABOR SAVING COAL BIN.

"I can prove there is a more convenient place," he said, encouraged by her twinkling eyes.

"Where?"

"Outside the kitchen door, I——"

"And have it covered with snow in Winter and soppin' wet from Spring rains or burnt to a crisp by the Summer sun, eh?"

The young man laughed. "No, I'd build a coal bin outside the kitchen and get the coal inside the room."

Mrs. Ware glared; her hands akimbo on her hips. "Well!"

"I'll build it," he ventured. "It will overcome unnecessary labor and be a convenient requirement.

"I doubt it!"

"How many tons of coal do you generally buy at one time?" he asked, poising a pencil above a writing pad.

"Six!"

He figured a few seconds and paused apparently delighted. "Then you'll require a box six feet long, six wide and 6½ feet high."

"How do you know that?"

His manner and tone both were assuring. "Because there are 39 cubic feet in a ton of coal and you must divide 39 into the number of cubic feet in a bin to get the number of tons it will hold. Thus: 6x6x6½ equal 234 cubic feet and divided by 39 equals six tons."

"How will the coal run out of a square box?"

"Believe me, Mrs. Ware, I'll overcome every difficulty. First, I'll build the floor on a post foundation two feet above the ground. Wood can be stored under that. The floor will slant toward the house at an angle of 60 degrees. Then I'll cut a hole through the wall 12 inches high and eight wide for the coal to run through. I'll line that hole with planed boards. Then, I'll built sides slanting from the sidewall to the back edge of the floor and make it 6½ feet high. Put on the back and top, which will have a trap door to shoot in the coal. The inside of the coal bin will be 122 cubic feet and hold three ton. The difference in 234 and 122 feet is due to the triangles cut out by the slant of the floor and sides."

Mrs. Ware smiled her appreciation. "And how do I get my coal out of the bin?"

"On the inside of the room, I'll make a sliding door to lift and drop with a lever. Put the coal hod under the shute, lift the lever and presto! The hod is filled with no labor to speak of and little inconvenience."

A. L. ROAT.

Mrs. Swiftly—"I wish Johnny would hurry. I sent him to the village for some Fels-Naptha Soap because I used the last for my wash this morning. I can't get along without it. I use it for everything. Johnny came home at noon and said to me: 'Say, Ma, I got a hundred in two studies this morning,' and when I asked what, he said: '40 for 'rithmetic and 60 for geography.' Isn't he a case?"

Anty Drudge—"He's cute, all right. But why don't you buy Fels-Naptha by the box or carton—then you'll always have it on hand."

If you have Fels-Naptha on hand, you're ready for any kind of work—washing, housecleaning, dishwashing.

There is nothing better than Fels-Naptha for washing flannels or woolens. It leaves them soft, white and woolly. And it's fine for colored clothes, too, either wool or gingham.

Use it the right way, in cool or lukewarm water.

Full directions are on the Red and Green Wrapper.

Fels & Co., Philadelphia.

Management in Housekeeping

"Efficiency" in the Farm Home

IF I had but two children, instead of a larger family, perhaps I might say something on system; as I have known the past few years what it is to care well for my family and do some outside work. Let me say to start with, I was 25 when married and had never done housework. I had worked as compositor in town and city printing offices for eight years before my marriage, so please don't think an office or shop girl can never make a good housekeeper or manager. I left a city office to become a farmer's wife. I told him he might be making a great mistake, but now, after 14 years of happy wedded life, the good man says he has always been satisfied and that I "make good."

I have always loved my home and family and been happy in doing for them. We have had some trouble financially, so I've tried to help, and it has taken some system to keep things going smoothly. I have raised from 400 to 600 chickens in one year, besides my other work, and some small fruit to see to. Now, as my husband is just a "hired man" after leaving our own place, I haven't the chickens and hens, but as we have been just 1½ miles from a village where a compositor was needed on the country paper I have worked for 19 months at this work, from two to four days a week (not real long days) and get two little girls off clean for school, make butter, do all my own work too, never buying baked goods.

I was pleased with what Mrs. Van said on page 866 about "do comb your hair" as soon as up in the morning. I can remember as a little girl my mother with her hair always combed as soon as she was up, then again, after dinner "clean up" with hair combed, dress changed and clean apron, ready for the afternoon's sewing. She had four little ones and often boarders too, to care for. When at home all day I aim to have housework done by two in the afternoon, unless in housecleaning or rush of fruit time.

Getting up early in the morning and rushing about all work that possibly can be done before children are up, is one big part of systematic housekeeping. When I had young chickens to care for they were all seen to before five in the morning. It did not interfere with the morning's work, and was better for the chickens, rather than keeping them shut up till late in stuffy coops. The only labor-saving device I have is a good washing machine. Water has to be carried in and out of the house, for no matter how hard an owner seems to want to get a good man no conveniences are usually thought of for the family. My machine saves time and back. Washdays I do up the regular work with the girls helping about dishes, dusting, preparing vegetables, etc., and by 11 o'clock washing is on the line and plenty of time to prepare dinner.

By having breakfast for two at six o'clock, on two other mornings at 6:30 I am ironing until eight o'clock and that work is out of the way ready for the children to help when their breakfast is over, with the dishes. They are little girls, so I let them sleep when not in school. As a sample of a Saturday's work, let me tell of last Saturday. Breakfast at six, separator was washed, butter churned and worked, jelly cake and rice pudding made, all by eight o'clock. The rest of the forenoon was devoted to the regular Saturday clean up ready for Sunday, as we do not work Sundays. The little girls are learning easy tasks and sewing without a continual scold from mother, and we try to keep our house all the time as if we were expecting guests. Too many farm women, I find, have such mussy-looking bedrooms and dirty dining tables. I have my table where it can remain set and always with white cloth and dishes on it. We all have days when we work hard and don't accomplish what we think we ought to; but with a regular system and eyes on the clock to keep us hustling we try to "keep ahead."

MRS. D. G.

Potatoes and Housework.

MANAGING the housework so as to save time requires forethought. This has been brought home to me forcibly this Spring in this wise. Summer drought for several years cut short our supply of potatoes, and we had to buy such as we could find, three different varieties. I found it took longer to prepare them for cooking than it did our own smooth, easy-peeling ones. One kind especially, said to be bug and blight proof, peeled about as hard as a green quince. The man of the house thought he would plant some of them, but the cook took good care he didn't get his hands on one of them. This Summer the cook is keeping a sharp eye on her seed potato patch which she personally conducts after the latest approved method. She began two years ago with one potato. She expects to have enough to plant the whole field next year. By the way, she gave us new potatoes for dinner June 28. Also green peas (wrinkled) both of her own planting. The cook has an inquiring mind. She wonders how many points palatability is allowed on the score card at potato shows, or are potatoes judged from a purely masculine standpoint? If you allow the women to tell what they want there is going to be ruction. The cook wants you to give the score as used in judging potatoes. She will be presuming to judge potatoes next.

C.

How Do They Manage?

DOWN in one side of our tenant house live Mr. and Mrs. Robertson. They have eight children but the one daughter (a capable girl and so good to the little ones) is married, and the oldest son is working away from home. That leaves the parents and six boys to live in six rooms, and a tent. Mrs. Robinson is not an exceptional housekeeper, by any means, and has limited means also. But she sits down to do everything possible, and she does every bit of work that can be done there out of doors. And though there is no fence between our grounds and the tenant house, in six years her boys have never annoyed us once.

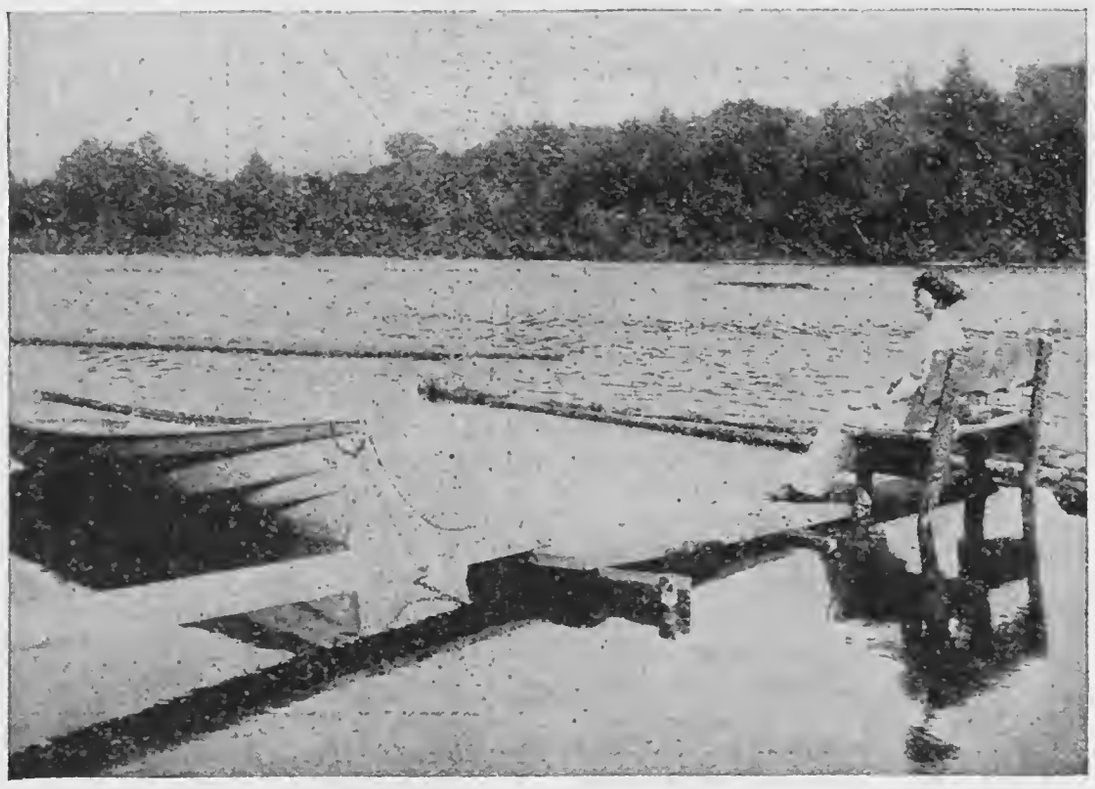
On the other side lives good Mrs. McNah. When her three sons were practically grown, she took five children of her cousin, when left orphans, to keep them from the State. Before these were grown up, a married daughter died and left five grandchildren to her care. The father is living and keeps a tenement where the older children sleep, but the oldest was twelve when their mother died. Mrs. McNab has a daughter who lives at home and helps with the work. Several of the boys work on the street railway, so are coming and going at all sorts of hours. The women keep everlastingly at it, and they all make mesh bags in their spare time out under the trees. Yet Mrs. McNab assures me that the only thing that really worries her is that we shall be troubled by the children's noise and hers because some days she has to "scold at them" so much. The question of housework by one for many seems to be a matter of the relative importance of things, separating the "must-be-dones" from the "ought-to-dos."

E. K.

Reflections of a Ruralist.

PARTNERS.—On page 777 is a little tale of partners. Here is another. A woman who had raised and lost a family, in her old age, broken in body and mind, went to live with a relative. After a year or more in the new home she astonished her caretaker by saying with much earnestness: "You are the only person who ever made a business of trying to find out what I want. Everybody else did what they thought I wanted or ought to want." The caretaker says it is difficult to get from this woman an expression of what she wants. The power to decide has perished from lack of use. For 45 years she was a man's partner. I fancy if the man mentioned on page 777 had tried to find out what his partner wanted instead of trying to convince her she wanted what he thought she ought to want, it would have been a different tale. In every true woman's heart is planted the spirit of self-sacrifice, the mother nature, but a true man will not take advantage of it. That story of excessive cleanliness reminded me of the Ohio woman who washed the pump handle whenever her husband used it.

C.



THE FRONT YARD OF A MAINE FARMHOUSE.

A Maine Front Yard.

All sorts of people take THE R. N.-Y., and they live under all sorts of conditions. Some of our housewives who live on the Western deserts have told us of roasting or broiling in the hot sun, obliged to economize in the use of even a thimbleful of water. The other extreme is shown in the picture herewith. This shows another R. N.-Y. home, or rather its front yard. This home is in Maine, the farm backing up or fronting on the Kennebec River, which flows on a roaring torrent in Spring, and a dignified stream in Summer. During the pleasant weather this river privilege is utilized by the housekeeper, as we notice in the picture. A little wharf has been built where the boats can be fastened, and there are rustic seats so that during the cool of a Summer's day the housekeeper, after her work is done, may sit on the river bank and watch the shadows and the passers-by. Those who are fortunate enough to live near a large river in this way will understand the great pleasure that comes to this household in its ability to utilize the water in this manner.

Cool Southern Housekeeping.

AS to keeping cool in Summer, I have a big back gallery, all latticed in, 12x30 feet, with a 12-foot ceiling, where we sleep except in rainy weather, In rainy weather we sleep in the house and eat on the gallery. In good weather we eat in regular scriptural fashion, in the yard, under our vine and our fig tree, as we have a good large native scuppernong grape running over an arbor about eight feet from the ground, and helped out by a couple of fig trees, and under the same arbor is a large lawn swing where the children play all day until they get tired and want a nap, when we put a light frame built like a wide ladder across the swing, pitch on a mattress and pile in the kids and let them snooze till they get tired.

But the cooking—that hot job. Well, we sport a coal stove, gas stove and fireless cooker, but the larger part of our Summer food is prepared on regular Old-Testament stoves, the brazier of coals. We don't call it that; we say a charcoal furnace, and have several, a couple of iron ones and a clay one; the latter exactly answers the description printed in THE R. N.-Y. some time ago of the cooking furnaces sed by the Armenians, Arabs or Persians, and is ahead of the iron ones in efficiency. It costs from 40 to 75 cents as to size, and sometimes we run a whole battery of furnaces, set around in the shade, and so avoid overheating either the cook or kitchen, cooking everything except cake or biscuits on them. The chickens do the housework by removing the scraps, and the children cannot spill food on the floor and grease it. Looks pretty lazy; well, maybe it is, but it is comfortable, and it looks more like efficiency than laziness, for the meals are prepared and cooked with half the work and double the comfort of a kitchen, and are fully as good or better cooked. We have learned how to be comfortable in hot weather, and save work, and it is worth trying.

Mobile, Ala.

The Woman At Law

[Under this heading we shall discuss the legal rights of women, particularly as regards thier property and their children. There will be direct answers to actual questions and general statements of law.]

Support of Children.

SINCE my husband will not agree to live in peace, rather leave than do so, I would like to know what he has to get on the property both personal and real, that is, what interest has my husband in both personal and real property where he leaves three minor children, one girl 19, one boy seven, one girl three, to be taken care and raised by me; leaving because he refuses to treat me right and leave me in peace.

S. B. B.

Virginia.

You do not give sufficient facts on which to base an answer. In the absence of any divorce or separation through the courts, the property rights of both on separating would be subject to contract between them. If the title to the property both real and personal is in either one of them individually, it would remain in that one even after separation, unless by contract they decided otherwise. The husband cannot leave his wife and children without being liable for their support. If you wish to separate, you should take into consideration that your husband must support the family, and this should be given due weight in a division of the property. If he leaves you with the care of the family, he should give you all of the property if it is not of great value, and a major portion if there is a good deal of it.

M. D.

To Take or Not to Take Under a Will

A man living in Pennsylvania makes a will, he having no children. After his death can the widow, not being satisfied with the will, break it, or must she accept it as made? What portion of a man's property in Pennsylvania can a widow hold by law, they having no children?

Pennsylvania.

G. M. K.

She cannot *break* the will unless her husband was incapable of making a will, but she can refuse to accept the provisions made for her by her husband's will and elect to take the property which would come to her if there had been no will, which, in this case where there are no children, the widow is entitled to the real or personal estate or both, to the aggregate value of $5,000 in addition to the widow's exemption ($300). If the value of the estate exceeds $5,000, the widow is entitled to such sum of $5,000 absolutely and in addition one-half the remaining real estate for life and one-half the remaining personal estate absolutely. If she elects to take against the will of her husband she must manifest her election by writing, signed, acknowledged and delivered to the executor or administrator, and recorded.

M. D.

Wages of Son.

1. Can a son get any wages for working over age? They claim they told him he could leave. 2. Was it legal for first cousins to marry about 28 years ago?

Pennsylvania.

A. S.

1. After the son becomes of age it is wholly a matter of contract between the parent and son as to whether the son is to get any wages. If the parents can prove that they told him he could leave, there might be a presumption that he remained and just worked for his board, and if the son wishes to prove that there was an agreement to pay him wages, he must show some express or implied contract to that effect. 2. Since January 1, 1902, it has been unlawful in Pennsylvania for first cousins to marry, and their marriage is void, but before that date there was no law against it.

M. D.

The Land of Fulfillment

A Story of Homesteading

By Rose Seelye-Miller

(*Continued from page 865.*)

CHAPTER VII.

"We don't need any hay land with the prairie open all Winter long—and such sleek cattle and horses," Nate put in simply because he wanted to say something, and he knew so little about farming.

"We've got to have a harrow or a disk, or something of that kind, and Jim says we can use his drill when he doesn't want to use it," Norm suggested thoughtfully.

"I don't think that will work," Nate objected decidedly, "because you will want to seed just the same time Jim does. I thought folks just went out with an apronful of seed and flung it around promiscuously and that was the end of it."

"I could broadcast the seed," Norm admitted. "But to think of sowing a hundred acres by hand, and then too, they say it needs to be drilled in deep, so it will not dry out."

"Let's get out our books and our spondulix and see if we can't afford a drill," Nate suggested gaily. The investigation did not lessen the expenses, nor create a larger fund. There was scarce enough in the exchequer, to buy the other absolutely essential things. But the time came, when they could have Jim's drill, and it must be confessed that it took both boys to do the first day's seeding, for the glory and the grace of it were past resisting.

"To think that we are seeding virgin soil, soil never yet cropped, and probably never trod by the foot of a white man, until we took possession of it." Nate exulted as he strode by Norm's side, for they took turns in driving and in watching the seeder to see that it poured out its slow tide of grain into the rich soil, properly. But their delight in sowing was of short duration, for Jim needed his drill, so Norm decided to begin breaking on the other side of the creek. Nate intended to help, when a "land" had been struck out, but he was not yet accomplished enough to do that himself. Nate was standing for a moment in the warm Spring sunshine, watching Norm as he labored with the oxen, when suddenly Norm flung up his hands, and beckoned to Nate. The beckoning was followed by a shrill whistle, and Nate started for his comrade on a swift run.

"Will you look at this?" Norm said wrathfully as Nate approached. "Now see me turn a furrow," and Norm called to the oxen sharply, held the plow with his whole strength, and strove to strike a furrow, but the plow share, slid out upon the surface, striking but an inch or two of earth, just enough to scratch off the thin coating of grass, and revealing a subsoil of shale.

"What's the matter with the plow?" Nate inquired innocently.

"It isn't the plow, it's the land. Did you ever see dirt like this?" and Norm bent down and lifted a handful of bluish looking soil.

"It doesn't look much like the other breaking," Nate admitted, lifting up and dribbling through his fingers the crumbly blue stuff.

"I knew the banks of the valley were slaty, but I never dreamed the whole section, was nothing but refuse," Norm said bitterly.

"Oh, that hundred we broke last Fall is the richest, blackest land you ever saw," Nate comforted. "I suppose we can reckon, on having some waste land, on such a piece as we own."

"I don't know of anything on the face of the earth that will grow on slate," Norm exploded, and turned his plow into the land in different places. "This runs back at least half way across this side of the creek."

"Begin on our eastern boundary line and see how it is there," Nate suggested. "Maybe we can break a little there for flax and corn," he spoke cheerfully enough, but in his soul he felt bitterly disappointed. To think that such good-looking land should have such a slight veneer of soil.

"If we'd taken the stony land you hankered for, it would have been better than this, for the stones would have been good to build with, but this!" and the scorn in Norm's voice seemed almost tangible enough to be seen.

Everything else was forgotten as the two boys went over that part of the land. It seemed as though at least half of the land filed on by Nate was of that shale-like formation, slightly covered with earth. Finally to the far east of the land the plow struck home to good soil, deep and rich and satisfying.

"I do wish we had a drill of our own," Nate grumbled that afternoon. "We are just about wasting our time, and the old settlers say it is the early crop that gets the rain, and makes the crop." He was passing the diminishing heap of buffalo bones as he spoke, and he picked up an immense skull bone with the horns still firmly fixed upon it, too firmly fixed to be easily wrenched away, there were half a dozen such there that had been discarded when the work of polishing had been at its height. "Dry bones and shale," he scorned, but he lifted the buffalo skull and carrying it to the shanty, fastened it above the door.

"The bones have been a mighty good crop, just the same," Norm said more cheerfully. "Can't you think of something to do with the shale?"

"Oh, I'll make some pots and pans of it, like mud pies, I suppose we could slime our buildings over with it for warmth, another Winter if we wanted to."

Followed a three days' rain, and after the rain came the warmest days of the Spring. The fourth morning when the boys were getting ready to begin breaking again, on the remaining good land, Nate's quick eye, espied something peculiar about the acreage already sown to wheat. He stared at it and glared at it, and then bursting out in a discouraged cry, he said, "Norm, look, the grain has all gone mouldy, look it's just white with mould! Is that what they call smut?"

Both boys dashed towards the sown land. Nate bent down and picked a bit of fungus. "Why I never dreamed that smut looked like this, why this is the rankest kind of mold I ever saw!"

Norm selected a larger specimen, and looked at it carefully, pulled away the whitish film that covered the stem, revealing gills as pink as a mayflower. "Mushrooms!" ejaculated Norm triumphantly. "We'll have a change of diet for a few days anyway. Look at the acreage."

"I had an idea," Nate said skeptically, "that mushrooms were manufactured for rich folks."

"Why I've picked 'em by the pailful and sold them in town for 25 cents per that quantity. We could get a supply of groceries with these if we had them where they'd sell."

Norm gathered a hatful, and Nate did likewise, and they bore them back to the shanty. "We'll have a feast for dinner," Norm said cheerfully.

The breaking went well that morning, and the two teams were turning over the soil rapidly. It seemed like good soil too, and both boys felt much more cheerful than they had done a few days earlier. Norm cooked the mushrooms at noon, and the boys were gorging themselves upon their rich delicacy, when a sharp, "Halloo!" broke in upon the meal.

A surrey full of men stood near the open door.

"We saw a gingham apron on the line," said Mr. Mansfield, from his place beside the driver. "And we hoped it might mean a dinner—we're simply famished." And he looked inquiringly at Nate and Norm, evidently a little disappointed not to see a woman also.

"The gingham apron, is merely for looks," Nate said genially. "It's a little joke of ours, and it does seem sort of comforting to folks as they pass, for they often think that a woman wears it."

"You can have dinner, though," Norm said. "My pal here is the cook, and he wears the apron."

Both boys began to loosen the tugs and unhitch the team, and Nate later went into the shack with Mr. Mansfield.

"Say, could you get me a buffalo skull like the one you have over your door? I'd be willing to pay well for it, to take back to St. Paul as a souvenir."

"Why yes," Nate said cordially, as he sliced the bacon thin, "I'm pretty commercial, but I think I can donate one skull without impoverishing myself very much."

Mr. Mansfield smiled a little." How are you fixed for machinery? Everything you need to work with?"

"No we haven't, we want a grain drill the worst way, but—" Here Nate stopped confused. "I guess I forgot myself," he added. "We boys baching here, all talk our affairs over so freely, I forgot for a minute. I might mortgage the land, but we found out the other day, that it is a large part shale, no good for agriculture—and we don't want to take a mortgage on land that isn't much good." Nate spoke lamely enough. Mr. Mansfield was a hard-headed business man, but he was quite taken with Nate's frankness.

"I sell machinery, and I'll sell you a drill just as cheap as anybody, and I'll take this buffalo head as a first payment. I'll put it up in my office and if I find anyone interested—maybe you could be induced to part with still another one."

"I guess I could find half a dozen, but we've picked out all the best ones long ago."

"I'll take two now, and you go into Wetasket this afternoon, and fetch out the drill you want. I'll take the balance of the payment whenever you're ready to pay it," and Mr. Mansfield scribbled on a piece of paper which he handed to Nate.

"I'm afraid this isn't very good business for you," Nate demurred, but his face was shining.

"It wouldn't be good business with every man, but I think it will be all right with a boy, who's honest enough to admit that his land is too poor to mortgage." Nate still demurred but he folded the paper carefully and put it in his pocket.

The simple dinner was ready when the other men came in with Norm, and it was served upon the hinged shelf without apologies. The men ate heartily of the bread and bacon, drinking their coffee out of tin cups.

"Real cream," said Mr. Mansfield.

"We've got bushels of mushrooms, if any of you care for them," Norm informed hesitatingly.

"Mushrooms!" cried all of the men, and Nate and Norm began peeling the fungi rapidly, and meanwhile frying in hot butter as they peeled. The men seemed well night insatiable, but after a time, Mr. Mansfield pushed back from the table.

"You live in effete luxury on the plains," he said. "I'd like to come out and stay awhile when the prairie chickens are ripe."

"Come," both boys urged. "There's fine hunting.

"Are we coming back past here," Mr. Homer inquired of Mr. Mansfield. "If we are I want to get a crate of those mushrooms to take back to the city with me—if the boys have them to spare!"

"You can have a wagon load," Norm said generously.

"They are selling in St. Paul for thirty-six cents a pound." Mr. Homer declared concisely. "You could reap a pretty reasonable harvest off your land, if you had a market for your mushrooms."

"There wouldn't be any market, and we haven't time anyway to peddle them about Wetasket. I'll fix up some though for you to take with you," Norm said decrying the idea of a possible sale.

Business

Actual Experience With Parcel Post.

THE following notes are from women who gave their address to the rural carriers as able to supply produce by mail:

I think the parcel post system is fine, and I will encourage and try to get others to make use of the privilege they have at their command. It has been so warm recently, and not having egg crates on hand suitable to ship in, has been one reason for my delay in sending eggs by parcel post. The merchants are paying better prices since they have been forced to do so. You can say to the merchant, "Now if you can't pay me the worth of my eggs, chickens and hams I can just send them by parcel post," and that has been a wonderful help to the producers. If we people in this community had a more direct mail route we could do better business. I hope to be of some help to you in the future. I would like to deal with reliable people, so there wouldn't be any delay.

Virginia. MRS. W. B. GENTRY.

I have done much business by parcel post with fine results. We have rural delivery by our yard gate, and a good carrier. I have never had any trouble with my parcel post matters. During the Winter months I sold lots of butter by parcel post to the first and second zones. I have almost all kind of products usually made on a farm, and I am very much interested in this business, and want to work up a better trade. But it seems hard to get in communication with the consumer, unless it is some friend or relative that you know in the city. I suppose they are the same as us—just haven't gotten acquainted with the matter. I have done more buying by parcel post than I do selling. Just think of it—we sit in our homes, do our shopping, and have the goods brought to the door for just a small sum.

Virginia. MRS. T. F. BOZE.

Lunches for Motorists.

THERE is much discontent evinced by the daughters of our farmers, due in a good measure to the lack of pin money or a certain allowance which might be used to buy the little extras so necessary to the dainty wardrobe. "Girls in town have a thousand chances to make pin money to our one," complained a farmer's daughter to a friend whom she was visiting in the city. The city woman was amused and frankly showed it.

"My child," she cried, "every farmer's daughter can have her private bank account if she so wishes. How about chickens, flowers, garden truck, canned fruits and even home needlework? Why the farm is alive with resources if you only wake up to them. Why don't you do what my niece Delia does? One day she was sitting on their big porch indulging in a fit of the blues because her father had refused her funds necessary for a course in the city school. Her interest was awakened by the approach of an automobile party who asked if they might have a glass of milk and some sandwiches. Hospitality was the rule of the farm, and she not only brought forth milk and sandwiches but also fresh berries and buns. She realized her guests' appreciation was genuine, and when one of the party slipped two silver dollars into her hand she shrank back as if to refuse. 'Take it, girl, and may you get many more ere the Summer is over.'

"The next morning Delia went to town and had a sign printed which read, 'Autoists' lunches served here.' Her home boasts a large lawn and a screened-in porch. She bought two hammocks, some lawn chairs, a wicker table and subscribed for many magazines. By taking a magazine agency she handled subscriptions of all her neighbors and got her own magazines at agent's prices. Besides paying her price for lunches many of her patrons left her a generous tip for the use of her magazines and porch, and she had not only been able to pay her way to school, but is building a bank account for herself. After a long trip, what is more refreshing than a fragrant cup of coffee or a cold glass of milk, accompanied by a tempting plate of sandwiches and cakes, and yet to the one who serves it it seems small indeed. Any ambitious girl can handle this work without assistance from her mother and without letting it interfere with her duties on the farm. I have been out with automobile parties many times when we would have been willing to pay 'most anything for a little lunch."

Wisconsin. M. G. DUNN.

Learn Your Husband's Business.

"I HAVE learned more about farming in the last two years," declares Mrs. E. S. Munger, of Crawford County, Pa., "than I did before in my life. My husband one day suggested the thought which comes to most of us when we get along past middle life. He said, 'You know little about farming, about crop rotation and about live stock, and what would you do in case I should drop out?' That started my thinking. It was true; I had given but little attention to farming, and with my children all but one married and away from the farm, and the youngest, a boy in his teens, still pretty young to have much practical experience, I wondered what we would do. I commenced reading, and THE R. N.-Y. was one of my first acquaintances. I now read every issue of the paper. My husband even declares that I know much more about systematic farming than he does, and we derive much more satisfaction and profit out of our farm work because of our planning it together on the basis of what we read."

A FARM WOMAN'S DAILY VACATION.

My attention has been called to a woman who had been a teacher, and she felt too proud to learn about the ordinary things of the farm when she married. A few years later her husband suddenly died; the valuable herd of registered Jersey and grade cows was sold at the price of the grades, for there was some question in matching registry papers to the animals. She tried a hired man, but he loafed and she failed renting. The good stock is now gone, and the farm appears a graveyard. With the woman's self-sufficient feelings there is no hope for her to return and continue the policy of the farm.

W. J.

Clarifying Beeswax.

I HAVE quantities of honeycomb or beeswax. Can you tell me how to clarify it, or prepare it for sale?

New York. MRS. F. A. M.

If you do not have sufficient comb and refuse wax to make investment in a mechanical extractor worth while, you can render small quantities satisfactorily in a wash boiler. Make a wooden rack of strips of hard wood of such size as to fit the bottom of your boiler and be held an inch or two above it; this to keep the bags of comb from touching the bottom of the boiler and burning. Place the comb to be rendered in burlap, or other loosely woven bags, fill the boiler nearly full of water, immerse the bags containing the comb in the water, cover them with a board upon which a heavy weight may be placed. Put the boiler upon the kitchen stove and let the water come to boiling. The wax will melt in the boiling water and rise to the surface, where it may be later taken off as a hard cake, or it may be dipped off and turned into any suitable dishes for cooling into cakes. As the wax cools, dirt settles to the bottom and may be later scraped from the cakes. The more pressure that can be put on the bags of comb while in the water the more nearly all the wax will be expressed but not as much can be obtained as by the use of a wax press, such as is sold by dealers in bee-keeper's supplies.

If you wish to refine this wax, as is done by manufacturers of comb foundation, the following directions are given in the "A. B. C. of Bee Culture": Fill a large iron kettle to about half its depth with water; add sulphuric acid to the water in the proportion of one part of acid to from 50 to 200 parts of water, the dirtier the wax the more sulphuric acid to be used. Place over a slow fire and when acidulated water is near to boiling add the wax that is to be refined. Keep hot for a few minutes and allow the fire to die down. As soon as all the particles of dirt have settled from the melted wax into the water, carefully dip off the clean wax from the top. It is not necessary to refine wax in this way to make it salable, and if it is done extreme care should be taken in handling the sulphuric acid; a most powerful corrosive poison.

M. B. D.

Discussion of Milk-room Wanted.

WE are making butter and find a good market, but are anxious to do away with some of the drudgery. I would like to see a discussion by people who have a milk room with power for churn and separator. We use dining room in Winter and cellar in Summer. Our well water is cold enough to use all Summer, but sometimes goes dry. We often have to put the cream in the well water over night this time of year. We have from eight to 12 cows, burn wood in stoves and so it seems a problem to plan a room that will be cool in Summer and warm in Winter. Some tell me to use the same power for washing machine, but I always object to having the wash anywhere near the buttermaking. We can use ice when necessary. MRS. A. J. S.

R. N.-Y.—This is a good question. Will our dairywomen tell us how to arrange such a room?

Market for Green Apples.

SOMEWHERE I have read that the confectioners who make candied fruits will buy the small apples that are culled to thin the apple trees in July. Can you tell me how I can find a market for them? M. W. A.

New York.

We know of no purpose for which the thinnings or green drops from apple trees can be sold. They are inedible and any candied fruit made from them would be condemned by the health authorities. Confectioners use fruit in various forms, sections of oranges and sometimes slices of apples being coated with candy, but this must be fruit of good quality.

Selling Holders and Good Nature.

"HOW far yon tiny candle throws its beams." As I was busy in the kitchen one morning there was a ring at the door. When I opened it, an old man, with his feet crippled from rheumatism, stood there, holding a box in his hands. With a smile he opened the box, and showed a pile of very neat gingham holders. He said he made them himself, and sold them because he did not want to go to the poorhouse yet.

"I go all through the White Mountains in Summer, and I make enough to keep me all Winter. Doctor says if I sat down in the chimney corner I'd get so cranky I couldn't live with myself."

"This is my kit," he continued, showing squares of gingham and of burlap, a spool of coarse thread, needles and a thimble.

When I had bought a holder he smiled the more, and went on to say, "Well, I meet a great many pleasant people on my travels, and if I do sometimes meet a sour one, the world is full of good folks just the same." He touched his cap, and with a parting smile said, "Good-bye."

I returned to the kitchen, feeling that I had met a gentleman and a philosopher. Moreover, I was encouraged to go on with my work in a more cheerful spirit. Who now dares to say of himself that he can have no influence for good in this world, even with strangers?

Vermont. ELIZA F. MILLER.

A Pippin that Traveled.

SOME years ago, while living in Virgina, I sent six Pippins to a friend in Panama City. This was before the days of parcel post. The six apples, with wrapping, pasteboard box and all, weighed just a fraction under 64 ounces (the limit for merchandise). The postage rate being one cent an ounce, it cost 64 cents. The apples arrived in Panama in good order, and attracted some attention, not because apples are unknown here—apples are on sale here nearly the whole year around, at prices ranging from five cents a pound to 10 cents apiece, but because these were different from any apples that had ever been seen here. The larger portion of the apples handled here are of the Ben Davis kind, that looks good in the show-window, and which will keep better than some varieties of good apples. Five of these lovely Pippins were eaten in Panama. The sixth one was forwarded to a person employed on the construction of the Madeiro-Mamora railroad, on the Amazon River, in South America. The mail route from here to the Amazon River is by way of New York, and the apple arrived there in perfect condition.

For distance traveled and variety of climate passed through, I think this is something unusual in the transporting of apples. Aside from the sentiment connected with this particular apple, this may serve as a practical lesson in what can be done with perfectly good fruit. The apples were perfectly ripe when picked. They were carefully wrapped separately in tissue paper, and laid in cotton batting in an ordinary pasteboard box. The distance traveled by this apple can be figured by referring to the map. The distance up the Amazon River alone is over a thousand miles.

Canal Zone. JUL JOHNSON.

TENDING CHILDREN.—I have tried several ways of making money at home—gardening, making butter, and raising poultry were some of the ways. They all turned out fairly successful, but there is more or less hard work and worry attached to each. The most successful thing I ever undertook was keeping children for mothers who wanted to go shopping or to some social affair. I lived on the car line between two good-sized cities three miles apart, and the car runs up and back every hour. So mothers had a good chance to drop me a line or call on the telephone, and I could be right at the depot to take the little ones, and they wouldn't need to get off the car. I charged 15 cents per hour during the Summer, and only keep them Saturdays and Sundays, except when there was a carnival, fair, or something of the sort going on; then I had regular hours, from eight in the morning until six at night I charged one dollar, and if later than that $1.50. But I never would keep any child later than 10 o'clock. The mothers were required to bring all the articles the children would need, and on rush days each baby's "bundle" was checked to correspond with the check on the baby. I always had plenty of toys to amuse them, and the older children were happy to run outdoors among the trees, where I had two big swings and tables and benches, where I always fixed lunch for them. Never a week passed but what I made from $2 to $5, and when there was something going on I have made as high as $25 a day. All the help I had was my little son, eight years old. He always liked to play with the little ones and keep them quiet. I always had all my work done up so I could give all of my attention to the children.

Butte Co., S. D. MRS. P. MUNTER.

OFFICER: "What's the matter with that soup you're turning up your nose at?" Private: "It's full of sand and grit sir." Officer: "Now look here, my man, did you come to camp to grumble or to serve your country?" Private: "Well, I did come to serve my country, sir, but not to eat it."—London Opinion.

"Short Stories"

All Sorts of Personal Experience With Food, Friends and Fixtures

Care of the Canary Bird.

THE canary for busy folks is no doubt what R. Y. N. is asking about. If most farm women would pretend that the canary was just a plain hen, and see that clean, mixed seed, grit in form of coarse sand, to be found on most farms, green food such as apple, celery, lettuce, chickweed or plantain, and fresh water were furnished the bird, all might keep these beautiful singers. They like a daily bath and clean cage but once a week will answer. But you cannot feed the canary to the cat and still keep it, for we tried it. They will endure quite an amount of cold, but draughts must be avoided. Any one who places the canary on the porch runs risk of both draughts and cats. In the Summer the birds moult like any common hen. A hard-boiled egg, mashed with a fork and fed mixed with cracker crumbs or alone will help at this time and also build up the bird for early Fall singing. Clean seed should be bought direct from bird store if that is possible, as the package goods are inferior. I learned these necessary hints in regard to the care of canaries from Germans who have bred them in their own country. I have raised canaries for ourselves and our friends for some years, and think any farm woman can do so. A. B. GILBERT.

New Jersey.

Women on Health Boards.

THE Woman's Journal comments on the fact that women should serve on boards of health. At Nutley, N. J., the report is that when Miss Annie L. Van Winkle was chosen a member of the local board three men resigned:

One choleric old gentleman in England declared that he would resign from a local Board of Poor Law Guardians if a woman were placed on the board, because, he said, no woman could understand accounts. But a woman was elected, and he had to submit. At the first board meeting that she attended, the accounts were rendered, as usual, and the lady's attention was attracted by an item of £5—about $25—which was set down as the price of a soup tureen bought for the paupers. The sum seemed to her excessive. She looked into the accounts, and unearthed a whole series of frauds. The board was being systematically overcharged for all the housekeeping supplies. When these facts were brought out, the choleric old gentleman said, with disgust. "How can you expect me to understand all these little domestic details?" The lady answered quietly: "I don't expect you to understand them. But, since you do not, isn't it well that there should be somebody on the board who does?"

Inexpensive Comforts.

IN the inevitable strenuous life on the farm, why not add a few holiday features for the Summer weather? With slight expense, a camper's tent, wire screened, could be put up under the trees near the working room, where the meals could be eaten, removed from the heat and the turmoil of the kitchen. This picnic life would rest and help the busy housewife, and the hard-worked farmer. Then, too, there is the old porch with the flat roof. Why not enclose the top with woven wire fencing, fill some ticks with straw, and use it for a hot weather sleeping porch—with or without an awning? Only those who have tried it, know the comfort and invigoration that come from sleeping in the open air. Don't get so busy with your work that you can't take a little holiday as you go along. I would also suggest, that the farmer's wife who wishes to attract Summer boarders, could find no more attractive "bait," than the "outdoor meals"—and the "sleeping porch."

H. E. FOULKE.

THE "CHRONIC KICKER."—Farmers who feel free to walk into the kitchen and tell mother what they want for dinner, should consider the case of William Morningstar, who got into trouble with a Buffalo Hotel. Mr. Morningstar it appears got tired of the hotel fare. He went out and bought some spareribs of pork, and gave them to the hotel chef, requesting him to cook them and send them up to the room. This was done, but the next Mr. Morningstar knew he was charged $1 for this service, in addition to his other hotel bill. The case went into court, and the jury decided against Mr. Morningstar, but as a matter of principle he carried the case up to the Court of Appeals, and this court has decided in his favor. The court decides that a hotel guest has a right to have spareribs cooked for him without being charged an excessive price, at least the court orders a new trial, chiefly on the ground that the jury decided the first case on evidence that Morningstar was what is known as "a chronic kicker." It evidently does not pay to have that kind of a reputation.

Plug the Melon and Eggs.

RELATIVE to Geo. A. Cosgrove's experience and inquiry on page 790, I would relate the following story my father tells. We had been using a bunch of boys hoeing corn—my father working with them. It had been his custom, when coming in from work, to stop at our melon patch nearby every evening and give each boy a melon. A few days after one of these occasions one of the smaller boys came over to where my father was milking one evening and after hanging around for some time with seemingly something on his mind finally blurted out: "Mr. Post you mind that watermelon you gave me the other day?" "Yes," said my father. "Well, that melon was green," replied the lad. Father hardly thought it could be, but as he had not plugged it he told the boy he supposed he owed him another then, so they went out to the patch and picked out another. A couple of days later the boy came back and after hanging around a little while finally said: "Mr. Post you mind that melon you gave me?" "Yes," said my father, "was that one all right?" "No," said the boy, "that melon was rotten." Well, my father took the boy out to the patch again, but he said, "Sonny, we'll just plug this one this time." If Mr. Cosgrove could only contrive some way to plug his eggs. By the way this boy's brother told me later that the little fellow didn't get to eat any of his melons—he had taken all three down town and sold them. C. H. POST.

Missouri.

ONE delightful day our Florida crowd were starting off for a day's outing. We were to drive to the boat landing. Four teams were full of happy people, and the driver of the first team had got in and spoke to the horse to start. Still he didn't move and every one wondered. On investigation he was still hitched to the post! B.

AUTOMOBILE NOTES.—Up in the hills of Western Massachusetts, back from the railroad, live a young married couple, special friends of ours. The man drives a mail and passenger route of 30 miles six times a week. Last Winter he kept three horses and it took all his time. This Spring he put on a five-passenger touring car and now has four hours a day at home to attend to his farm. Also he has taken a number of parties out in the evening. The local storekeeper has also purchased a similar car, as it will save so much time on his weekly trips to the nearest town. The storekeeper carried only a few standard articles in stock, but every Saturday makes a trip to the city where he will get without extra charge, whatever is wanted. The rural driver intends to buy horses next Fall, when they are cheap, use them during the Winter and sell them in the Spring. The hill roads are now filling during the Winter. S.

EXTRACTING BEESWAX.—I noticed inquiry how to extract beeswax. Here is the plan I have used several times: Pack the comb in a small flour sack as tight as possible. Put a rack made of lath in bottom of boiler, place sack on it, and weight down with flat stones. Put in water so that it stands two inches above rack, and boil for an hour. Set off and let cool till next morning. The wax will be in large cake on top of water. Break it up and put in small dish on back of stove to melt and then let cool again. If you wish some small cakes pour some in teacups while melted. C. E. DEGROFF.

Missouri.

A NEIGHBORHOOD GARDEN.—Mary Ann is a young factory girl nearly 20, she looks about 12. She is one of a family of five brothers and sisters whom a big-hearted Irish cousin of their mother's took in to keep them from "going on the State." Mary Ann has always worked very hard, and finds factory work easier than what she did at home. She wanted a garden, but had no money to spend on it. The fact being known, the next-door neighbor contributed Petunia and hollyhock plants, some Iris roots and lilies-of-the-valley. From the old Fairbanks homestead came periwinkle, day lilies, columbine and four kinds of old-fashioned roses, which all decided to live. Mrs. Cook gave Sweet William, some nasturtium seed and several kinds of hardy Phlox. Cousin Grace planted her first garden this year and put in the seed about 10 times too thick, she was very glad to contribute superfluous plants of Verbenas, Drummond's Phlox and Japan pinks. Mary Ann's brother got the ground ready, the neighbor who knows how showed her how to plant her gifts, and her garden is an established fact, with little time and trouble and no expense. Perhaps there are other Mary Ann's who would like a garden. K.

BEEF PIES.—Our family like little pies made of cold roast beef, chopped and thickened in a gravy. Make a rich biscuit dough, roll as thin as pie crust and cut in six-inch squares. Put one square into a gem or pastry pan, with the four corners hanging over, fill with the beef mixture, and fill the corners over to cover. These can be easily warmed over. B.

WHEN SILKS SPLIT.—The Wisconsin Station gives the following test for silk: "Why did your last year's silk split and crack? Because it was weighted. You might have tested it easily before purchasing and saved both money and worry. A bit of the silk and a match are all you need for a sure test. Light the match and apply it to the fabric. If it holds its shape the silk is adulterated with some of the various minerals so used. If it melts down in burning and runs together in a puffy mass the silk is pure."

KEEPING THE MILK.—One farmer has solved the problem of keeping his butter and milk cool in the hottest of weather though many miles from ice. From the pantry down to a depth of four feet below the cellar floor he built a dumbwaiter shaft. This hole below the cellar floor was cemented on the bottom and all the sides, and being below the surface of the cellar it was always very cool. Not only did this method keep things cool, but it was such a step saver to be able to put all the supplies on the dumbwaiter and simply lower it into its under-cellar.

Iowa. MRS. C. A. RHOADS.

COUNTY VOLUNTEERS.—In Massachusetts the Hampton County Improvement League has started what is called an Organization of County Volunteers. This means working among the boys and girls of Hampton County. The plan is to interest them in their homes, on the farms, and through the school and church, as a foundation for a larger organization. The League started with five towns as an experiment, but is spreading rapidly. The boys and girls will be taught to play as well as to work, and all that, and the present outlook is for a most successful organization among these volunteers.

FOR THE INVALID.—A strap or rope suspended from the ceiling or fastened to the foot of the bed is often a great help in enabling the patient to raise or to support himself if confined to the bed on account of a disabled limb. For the nurse it lightens the burden of the patient's weight in lifting him. A clean blotting-paper placed under cups, glasses and ice-pitcher on the invalid's table will keep the cloth fresh and tidy and lessen the laundry work. Mechanical puzzles often afford excellent entertainment to a convalescent whose eyes are not strong enough for reading or writing.

Wisconsin. JOSEPHINE E. TOAL.

MAIL BOX ON A WHEEL.—One ingenious farm woman who disliked to see her corner decorated by the unsightly row of mail boxes which were placed at all sorts of heights and angles, induced the man of the house to construct a new arrangement for them that would prove more attractive to the passerby. Horizontally on the top of a post he fastened an old wagon wheel, bolting it on so that it would revolve. The mail boxes were fastened on the rim of the wheel at certain intersections. From the spokes of the wheels were hung short straps with snap ends, so that parcel post packages could be snapped securely on. Boxes and wheel were painted red, with the owners' names put on in neat white letters. Beside being a good-looking arrangement it delighted the mail man, as he could sit in his buggy and turn the wheel to any box he desired. MRS. C. A. RHOADS.

Iowa.

TRAINING CHILDREN.—I think that a good study for the "Woman and Home Department" would be the care and management of home and children. I think perhaps it might be a help to some. A child should be taught from childhood—girls as well as boys—to be familiar with all kinds of work, both in the home and on the farm. They can attend to small duties while young, and what they are taught in childhood they never forget. They should have a small task set aside for them each day, and their mother should see that they do it right. Your home work can be planned to suit yourself a good deal, giving you days that you can spend with your children, and be young with them. There can be many interesting hours spent with your children right on the farm. And they are a good deal better right there with you than you not knowing where they are. I have a grandson and two granddaughters, and I sincerely hope they may be brought up on the farm as my two daughters and son were. MRS. C. W. C.

Rhode Island.

"The Favorite Hen"

When we offered to enter a number of hens at one of the egg-laying contests we had no idea that the suggestion would prove so popular. We were limited to 30 hens and a few substitutes, but within three weeks of the offer the following named women made application:

1. Mrs. Daniel Thomas, Cortland, N. Y.
2. Mrs. Carrie Chaffee, Sullivan, N. Y.
3. Miss M. E. Pierce, New Haven, Conn.
4. Mrs. S. O. Travis, Westchester, N. Y.
5. Mrs. K. H. Smith, Tioga, Pa.
6. Mrs. E. P. Andrews, Ontario, N. Y.
7. Mrs. F. M. Earl, Fairfield, Conn.
8. Mrs. C. F. Weaver, York, Pa.
9. Mrs. Lewis J. Happich, Chenango, N. Y.
10. Miss Mary B. Brooke, Montgomery, Md.
11. Mrs. Stephen Wilson, Steuben, N. Y.
12. Mrs. L. G. Robison, Otsego, N. Y.
13. Mrs. Alice G. Parsons, Hampshire, Mass.
14. Mrs. A. B. Thompson, Bergen, N. J.
15. Mrs. Clara Eddy, Ritchie, W. Va.
16. Mrs. Robert H. Wood, Herkimer, N. Y.
17. Mrs. Walter Fletcher, Madison, N. Y.
18. Mrs. Carrie M. Bliss, Loudonn, Va.
19. Mrs. Edwin Walker, Middlesex, Mass.
20. Mrs. W. R. Merrick, Norfolk, Mass.
21. Mrs. E. S. Marlatt, Warren, N. J.
22. Mrs. Josephine Hollenback, Berks, Pa.
23. Mrs. Theo. F. Lees, New Haven, Conn.
24. Mrs. W. E. Phelps, Bradford, Pa.
25. Mrs. R. W. Stevens, Saratoga, N. Y.
26. Mrs. Cecil Farnham, Hancock, Me.
27. Mrs. R. L. Predmore, Middlesex, N. J.
28. Mrs. A. J. Skellie, Otsego, N. Y.
29. Mrs. Eldin Landers, Oneida, N. Y.
30. Mrs. Edgar Chaffee, Orleans, N. Y.
31. Mrs. J. F. Kahl, Wexford, Mich.
32. Mrs. E. C. Gabriel, Suffolk, N. Y.
33. Mrs. Chas. Tlmerman, Cortland, N. Y.
34. Mrs. Joseph di Fabrizio, Atlantic, N. J.
35. Miss Elizabeth A. Woodman, Bucks, Pa.
36. Mrs. Andrew J. Wilson, Hartford, Conn.
37. Mrs. Edwin C. Smith, York, Me.
38. Mrs. N. D. Rand, Ulster, N. Y.
39. Miss Edna M. Porter, Niagara, N. Y.
40. Mrs. L. D. Prindle, Chittenden, Vt.
41. Miss Ethel A. Pierce, Sullivan, N. H.
42. Mrs. Emma H. Wood, Washington, N. Y.
43. Mrs. A. N. Conell, St. Lawrence, N. Y.
44. Mrs. J. Schwenk, New Haven, Conn.
45. Miss Jessie A. Close, Cayuga, N. Y.
46. Mrs. O. E. Leach, Fulton, N. Y.
47. Mrs. C. J. Leach, Fulton, N. Y.
48. Mrs. L. E. Hilborn, Steuben, N. Y.
49. Mrs. G. L. Rothgeb, Frederick, Va.
50. Mrs. W. S. Walters, Berrien, Mich.
51. Mrs. V. D. Miller, Geauga, Ohio.
52. Mrs. W. W. Shay, Haywood, N. C.
53. Mrs. J. N. Ludington, James City, Va.
54. Mrs. D. F. Hiler, Steuben, N. Y.
55. Mrs. C. D. Wood, Vigo, Ind.
56. Miss Martha A. Small, Waldo, Me.
57. Mrs. L. C. Litchfield, Addison, Vt.
58. Miss Tillie B. Cloud, Chester, Pa.
59. Misses Osler & Wilcox, Chemung, N. Y.
60. Mrs. W. A. Paust, Saint Clair, Ill.
61. Mrs. F. Hansen, Mercer, N. J.
62. Mrs. N. M. Congdon, Madison, N. Y.
63. Miss Julia Bartlett, Tolland, Conn.
64. Miss Althea M. Slter, Broome, N. Y.
65. Mrs. C. L. Todd, Henrico, Va.
66. Mrs. Herbert Hood, Caledonia, Vt.
67. Mrs. Effie Mann, Columbiana, Ohio.
68. Miss Lillie J. Babcock, Litchfield, Conn.
69. Mrs. Fred Millward, Mercer, N. J.
70. Mrs. H. G. McElheney, Allegany, N. Y.

Make a Fair Selection

Now we regret that we cannot accommodate all in this contest. It will be necessary to select 30 or a few more out of this number. We wish to make such selection as fair as possible, and it seems to us the wisest plan to ask the women who are here named to suggest a method which will prove satisfactory. Some of these women have already volunteered to withdraw. Others have made only a tentative application. We find that some may be classed as breeders or professional poultry women, while others are quite well-to-do. It was our original plan to limit these entrances to farm women who have developed good farm flocks, yet cannot be called professional breeders. We wish to be fair and just to all, and our regret is that we cannot find room for all the hens that are offered. In making a final selection we wish to be absolutely square and select the most deserving applicants, and so, ladies, we will leave it with you to select the requisite number. Will you please give us your suggestion?

Live Stock and Dairy

PROFIT IN PORK.

I AM interested in raising pigs. My estimate of the profit on eight pigs fed last year, from November 1 to July 15, was something over $100, the pigs being six weeks old November 1. As this seems too much to me, I ask you to estimate the amount of feed in pounds per day an average pig six weeks old will consume, beginning November 1, and ending July 15. I am now feeding bran, middlings, oil meal and tankage about as follows: November, one pound daily; December, two pounds daily; January, three pounds daily; March, four pounds daily. I expect to continue this ration until May 1, when I shall substitute hominy meal for the middlings, and a little later germ oil meal for the linseed oil meal. We also feed small potatoes and clover chaff. Will you advise me what you think of my ration and the amount I am feeding; also estimate the number of pounds daily for the months of April, May, June and July, at which time they should weigh 300 pounds each.

New York. G. C. B.

I do not think that you over-estimate the profits from eight pigs at $100. There are so many factors to consider in determining such net income, the results depending largely upon whether you have grown and fed your own waste products, or whether purchased food stuffs have been obtained at market prices. It would be difficult to determine accurately the number of pounds of feed required per day as is suggested, for hereto are a great many factors that should be considered. Henry's "Feeds and Feeding" gives the following standards for growing fattening swine:

PER DAY PER 1,000 LBS. LIVE WEIGHT.

ANIMAL.		Digestible Nutrients.					
Age in mos.	Av. live wt. per head lbs.:	Dry matter.	Crude protein.	Carbohydrates.	Fat.	Sum of nutrients.	Nutritive ratio, 1:
2- 3	50	44	7.6	28.0	1.0	38.0	4.0
3- 5	100	35	5.0	23.1	0.8	30.0	5.0
5- 6	150	33	4.3	22.3	0.6	28.0	5.5
6- 8	200	30	3.6	20.5	0.4	25.1	6.0
9-12	300	26	3.0	18.3	0.3	22.0	6.4

You will note from the above that the proportion of feed per 100 pounds live weight is greater in a younger animal than in an older individual, it varying from 4.4 pounds for the younger animals per 100 pounds live weight to 2.6 pounds for the 300-pound 10-months-old pig. A safe rule is to permit animals after they weigh 100 pounds to eat all that they will clean up with relish if it is desired to fatten them most economically and in the shortest period of time.

After the pigs have a well-grown frame and weigh, we will say, from 125 to 150 pounds, I doubt very much whether it pays to feed anything but corn and digester tankage. Certainly bran is too expensive, and tankage is a more economical source of protein than oil meal, and in my judgment corn or hominy will supply heat, fat and energy more economically than middlings at their present price. Therefore, I would suggest that when the animals are put in the fattening yard, or even if they are running out and have green forage available, that they be put strictly on a ration of ear corn and digester tankage, using from five to 10 pounds of the tankage for each 100 pounds of corn fed, and thus eliminate the bran and other ingredients suggested. It is well to have such a variety during the early stages of growth of the pigs, but it is not necessary to have such a variety during the time when the pig is putting on the last 150 pounds of his weight.

There is very little food value in potatoes, and they should preferably be cooked in order to decrease the amount of moisture before they are fed to swine. Clover chaff might take the place of a portion of the tankage, but it is rather bulky for fattening animals. It does very well for brood sows, growing pigs and breeding animals, but it is good judgment to supply a more concentrated ration for shotes that are being fattened for market. G. C. B. should bear in mind that he should keep before his animals a mineral mixture, and the following should be kept before the pigs at all time in an open trough.

Charcoal	5	lbs.
Salt	5	"
Bone Meal	5	"
Ferrous Sulphate	3	"
Sulphur	2	"
Air-slaked Lime	5	"

It is necessary to keep all the pigs in a herd growing daily, and at no time should a shote intended for market be marking time. At least a pound of gain per day should be secured, and even this increase does not satisfy our best feeders.

F. C. M.

DAIRYING OR BEEF MAKING.

EASTERN farmers will be interested in reading the following statement of the comparative claims of dairying and beef making in Kansas. The same thing would not be true of Eastern farmers.

REGISTERED HAMPSHIRE BOAR, BRED IN MAINE.

Where the work is done on a small scale, dairy cattle are more profitable than beef cattle, so said W. A. Cochel, head of the animal husbandry department at the Kansas State Agricultural College. One man can do all the work necessary to care for about 100 beef cattle, according to Professor Cochel, while 10 dairy cattle will keep one man busy. Investigations show that most of the dairying is done by men who are from 25 to 50 years old, and who have large families, while few beef breeders are less than 40. The same investigations show that most dairymen are men with families, and that many beef producers are bachelors. A bachelor would be at a disadvantage in trying to run a dairy farm in competition with a man with a large family, because the work on the dairy farm is such as to furnish occupation for every member of the family. On the other hand, production of beef gives a man an opportunity personally to supervise a much larger investment.

Another interesting fact mentioned by Professor Cochel is that the dairyman is always looking forward to the time when he can retire from active work and enjoy the profits he has made, while the man who grows beef cattle is planning for the time when he can feed an extra carload or two. The dairyman is tied down to a routine of work that does not allow him to mix with his fellows in the way that the beef man can.

Horse With Cold.

WHAT can I give a horse that has been shipped here from the West, and has a cold, or a shipping fever, as some people term it? R. E. B.

Pennsylvania.

Take no chances in such a case, as glanders may be present. For that reason we should not feel justified in prescribing treatment and a graduate veterinarian should be employed to make an examination and prescribe if glanders is not found present. We can only prescribe when symptoms are described in detail. A. S. A.

B

Why Feed Flies

You can get more cow's milk, more horse strength, more hog fat, if you keep off flies.

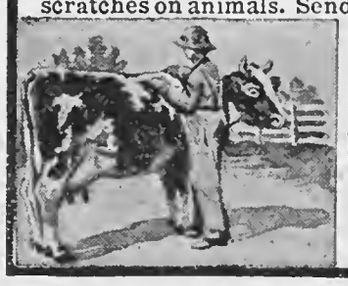
Use

Sirenia Oil

It is feed economy and animal satisfaction. Sirenia is made of pure oils. Sirenia is applied with a cloth, no sprayer neeessary. Ask your dealer for a dollar can of it. Do not buy a substitute. There isn't any. If your dealer doesn't handle, send us his name and a one dollar bill and we will send a one dollar can, postpaid.

We Will Refund Your Money If Not Satisfied

Drives flies from cattle and horses, fleas from hogs and dogs, lice from poultry, ticks from sheep. It will also heal sores or scratches on animals. Send a dollar now; or write us a card for the endorsements of users who wouldn't be without it.



United States Whip Co.

Westfield, Mass.

Quinn's Ointment

The Mild Absorbent

Painless—safe—easy to apply—no scar. Horse can be worked. Use for splints, bog spavins, curbs, wind puffs, swelling of throat and glands and all other flesh enlargements. Excellent for wire cuts and old sores. Write for information. For sale at druggists or direct. Price, $1.00, delivered.

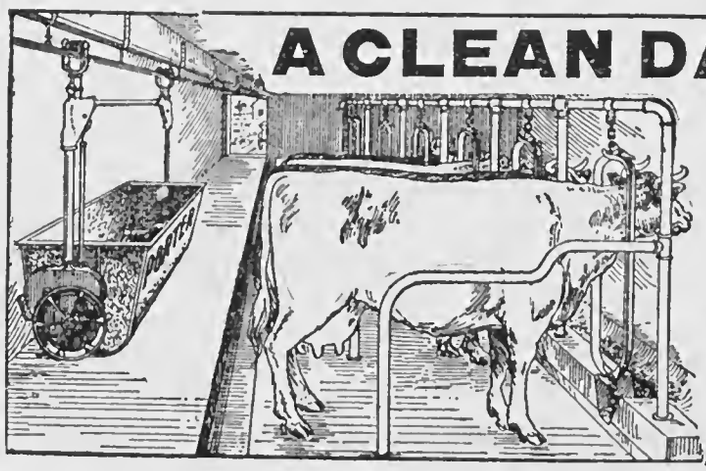
A CLEAN DAIRY BARN With Half the Work



By using a Porter Litter Carrier. It works on our Columbian Steel track, is easy running and will carry heavy loads. Our Perfect Cow Stanchions line up the cows without interfering with their comfort.

Porter Steel Stalls give perfect ventilation and light throughout the barn and make it easy to keep the cows clean.

We also make the celebrated Porter Hay Carriers and Barn Door Hangers. Send for catalog of our Perfect Barn Equipment.

J. E. PORTER CO., Ottawa, Ill.

SHORT DAIRY NOTES.

THE R. N.-Y. asks, on page 890, if fat cows give richer milk than thin ones? Yes, and no. If a very fleshy (fat) cow is taken very soon after freshening, and a test of her milk made, and then for a week about all of her food taken from her so to make her live "off from" herself and result in a feverish, abnormal condition, the amount of fat in her milk shows a very large gain in per cent., but as soon as the feed is restored, and normal conditions return, the fat drops back into its natural richness and there remains until the flow of milk in advance lactation slackens. The water in the milk shrinks in weight faster than do the solids. As was exemplified at the Missouri station, a fat cow can be starved for a few days into giving milk that is very largely cream.

In this section, several who have tread powers, use the herd bull as power, instead of gasoline. Near me, Mr. Frank Ruewee, a noted Holstein breeder, uses his $2,500 sire, not only to run the farm machinery, but the milking machine as well, and a capital "power" he is. By the time the milking is done, the separator ungeared, the water pumped, and the grindstone no longer needed, a well exercised bull goes to his stall, not only to take a rest, but with all thoughts of doing violence to anyone far from his mind. He is not only benefited, but his worth in the herd is greatly increased.

A neighbor who has a small gasoline engine to run his milking machine, conceived the idea of getting a small electric generator, storage battery, and wire his buildings for an electric light plant instead of buying a complete, sold-by-agent electric lighter. A man who was familiar with "wiring" was found, the needed supplies bought here and there of the manufacturers—Cleveland has scores of them—and the plant installed with 60 lights divided up between his own and the tenant house, the barns and milking stable, and in other buildings, and here and there a light about the grounds. It has been a marked success. He tells me that the expense was very moderate for the benefits received and the safety part, is not inconsiderable. Two other men have small streams where a water motor is installed, instead of the engine, and they too are confident that they "lead."

JOHN GOULD.

FAT COWS AND FAT MILK.

SOME of our practical dairymen feel sure that cows, when fat or in high-class condition, will naturally give richer milk than when thin or poor. These men do not claim that fat can be fed into the milk to any extent, but they feel sure that a fat cow or one that is smooth and plump will naturally put more fat in her milk. Will you tell us what you think of this proposition?

It's the Way She Is "Built."

THE old, old question as to whether or not it is possible to change the percentage of cow's milk by the character of her feed is still debatable in some ways. All carefully conducted experimental work, notably the classical data secured at Cornell some years ago, points to the same conclusion: viz., that the percentage of fat in a cow's milk is dependent upon her food supply to only a very slight degree. Abundant and correctly balanced rations will surely increase the amount of milk sometimes to an astonishing extent, but it is doubtful if the per cent. of fat will be regularly changed. Indeed, the better ration has not unfrequently been followed by slightly less per cent. of fat. On the other hand, the Holstein breeders, in their Advanced Registry testing, seem to have found that if a cow has stood dry a long time and accumulated a great surplus of fat stored in the body, she will unquestionably for at least a brief period following freshening, give milk containing a higher percentage of fat than her normal flow throughout the year. I think we might answer the question thus. If a cow is decently well fed and nourished, we may hope to greatly increase her milk yield by skillful feeding, but the per cent. of fat is as likely to decrease as it is to rise. But the very poorly fed or semi-starved cow will not give milk as rich as if she is very fat at calving. The truth seems to be this: The per cent. of fat in the milk of a cow is a question of the structures of the cells of the udder rather than nutrition. A cow gives milk with a certain fairly definitely fixed composition because she "is built that way."

JARED VAN WAGENEN, JR.

Keep the Ribs Covered.

I THINK it is a well-established fact that you cannot feed fat into milk to any appreciable extent, provided the cow is in a good, thrifty, normal condition and has been fed for some time on a good, balanced ration, but I believe all those conditions are necessary in order to have the cow give milk of normal richness. I think it has been shown, and it stands to reason, that a cow maintained on a poor ration, not properly balanced, changed to a plentiful amount, properly balanced, has shown an increase of fat in her milk, simply because she was not up to her normal productive capacity while on the poor ration. I believe too many dairymen are afraid of a little surplus fat on the cow's ribs, and I think most cows are so thin in flesh that they are not up to their normal ability. Some of the best producing cows I have ever known were cows that the average cow man would pronounce too fat, and these cows were noted as producers of high-testing milk. I do believe a cow kept good and fat will not only give more milk but richer milk.

Wisconsin. F. R. CONSTANCE.

A Thoroughly Nourished Cow Best.

IT is very difficult, indeed, to get accurate data upon this question. There are, however, some general indications that point very strongly to a positive answer to your question. The time during the lactation period when it seems to have the most marked influence is during the second and third months after parturition. I do not think it is altogether the amount of fat on the body which exerts an influence, but partly due to a system of feeding which maintains the cow during the last two months of gestation in a strong, thoroughly nourished condition. Parturition should be a mere incident in the yearly life of a cow, and will be if she is as well fed when dry as when in full milk. Of course the prospective mother, if full fed, will usually take on fat before freshening, and generally fat is an indication at that time of strength and vigor. It is probably safe to say that it always will be, if put on with the usual milk ration, or probably what is better and safer to use, either br .. or oats, to which is added one pound daily of oil meal. Very little danger of fever under such feeding if good hay and silage are judiciously fed.

If a cow freshens and is thin and not strong she will not give as rich milk, and usually not as much of it as a cow freshening under full feed. For a few days before freshening the mother should be put on less feed, but not enough to lessen her desire for water, which is the great equalizer or balance wheel for the system. Proof is abundant that a change of ration cannot suddenly improve the fat content; on the contrary, any radical change is likely to disturb the system and reduce the fat.

Some day we shall all learn what some have already learned—that a cow has no rest, and must be kept in prime condition every day from birth to finish, and that the ability to produce both quantity and quality must be first bred with the calf and then fed into her without a skip. Watch out among our most successful breeders, and you will discover with no exceptions whatsoever that they push every animal from birth to get a large, full development of body and digestive capacity. The ability to consume to advantage a large quantity of feed is no accident but as much a piece of education as to educate a boy or girl to digest big mental problems. They cannot do it if they are in and out of school to suit somebody's fancy; neither can a calf become a producer of much milk and much fat if she is fed on the installment plan. I hear it on every hand that it doesn't pay. If my observation is correct, those who feed steadily as a whole are the prosperous dairymen, because they will not continue to feed inferior cows. Yes, my experience and observation tends to prove the assertion that a thoroughly nourished cow will give a higher per cent. of fat than if not thoroughly nourished, and it is in harmony with every law of animal life.

New York. H. E. COOK.

DAIRY CATTLE

FOR SALE—Two Registered Jersey Cows due to freshen in September. One's test is 5%; other, 5.20%. A delivered price by express will be given. Also an extra fine Ayrshire cow, due to freshen in March, now giving 35 pounds of milk per day. THE CASKEY FARMS, Richmondville, N. Y.

HIGH GRADE HOLSTEINS
The best are the cheapest. Why not have that kind? We have 200 large, well bred cows that are heavy producers. Some fresh and others due within 60 days. Tuberculin tested. Come and see them.

Bell Phone 14, F.5.

Tranquillity Farms
Offer a very handsome Bull Calf, four months old, two-thirds white. Extra Large. Sired by a young bull, who's Dam made over 33 lbs. butter, and 750 lbs. milk in 7 days, nearly 9,000 lbs. in 100 days. Dam of calf over 19 lbs. butter, as heifer with first calf. Every animal in calf's pedigree a large milk and butter producer. Sent anywhere in the United States, express prepaid, on receipt of check for $200.00. A Show Animal.
A. G. Danks, Mgr., Allamuchy, N. J.

Purebred Registered
HOLSTEIN CATTLE
If your cows produce only about 4,000 pounds of milk per year and 160 pounds of fat they are practically worthless; 350 pounds of fat per cow per year should be your minimum requirement.
No matter how poor your present herd is you can easily raise it to this standard in a few years by the intelligent use of a well-selected purebred Holstein-Friesian bull.

Day after Day, Year after Year,
PRODUCTION COUNTS
It is not what a cow can produce in 7, 14, or 30 days, even in a year that determines her value to the farmer, it is what she can do in a lifetime.
Brown Swiss Cows rank high in average production and are regular and persistent breeders and producers. Year in, year out, they make good records and raise good calves without any coaxing or pampering. If interested, we will send you an illustrated booklet.
The Brown Swiss Cattle Association
IRA INMAN, Secretary BELOIT, WISCONSIN

That Prize Baby of Yours

His Feeding and Care

Tender Young Stock

REFERRING to the article on page 641, entitled "The Significance of the Sign," while I must now profess ignorance as to what is meant by that, I should say from the facts presented that "Gertie" had brought her baby up according to the approved modern method, viz.: of weaning babies when they are nine or 10 months old. The reason she had no trouble in weaning him, and that he took to being fed with a spoon, was probably because he had been given water with a spoon regularly twice a day from the time he was a few days old. At any rate he had had it often enough to accustom him to it.

My doctor told me to accustom my children to a bottle by giving them hot water (as hot as a mother's milk) whenever they had colic, hiccoughs or indigestion. This they would take if starved into it, which is in no way as harsh as what "starved into it" would seem to express, for babies should not be fed while having any of the above mentioned things the matter with them. In giving hot water for those troubles there are no bad after effects as when medicines of different kinds are given. The advantage to be gained by getting them used to the bottle is that when they are weaned they can be put in their crib each time they are fed and the bottle propped up so the milk is always ready at the nipple, and no air will be drawn in to give them colic. Naturally this is a great saving of time to the mother besides being good for the baby, for when it is nap time and night time he will generally fall off to sleep as soon as he finishes his bottle. The nipple on the bottle should not have a large enough hole in it to allow the milk to come out except when the child sucks on it.

I would like to make a plea to farm mothers to give their babies more fresh air by putting them to sleep in the daytime, Summer and Winter (except in bitter weather) out of doors, and having the windows wide open at night in the bedrooms. They will be so much healthier and so much less care when teething and even beyond that age. Both my children were delicate at birth, but now they are strong and sturdy. This has just come from fresh air, plenty of sleep and proper food for their age. Up to the time they were five years old they went to bed at six o'clock, taking a nap in the morning, and I never allowed them to have pastry of any kind, nor pork in any form, until after they were seven. Tea and coffee they will not be allowed to have until they are 16. When anything outside of milk or buttermilk is wanted they are given cocoa, which is very healthful and nourishing.

If country mothers who have so much to do would train their babies to regular habits in the way of eating and sleeping, and would not carry them around in their arms so much just because they cry a little, they would find it much easier for them, for they could plan their work accordingly. I know this is so from both experience and observation.

MRS. FLORENCE BELLE.

Give the Baby a Chance.

I FIND many children in the country suffering cruelly from improper feeding and care. It is the result of ignorance rather than anything else. While at a picnic last Summer a woman had a 10-weeks-old baby that cried all day with colic. Yet that mother told, somewhat boastfully, I thought, how fond the tiny thing was of ice cream. She was not a young woman but a middle-aged, with six children older than the infant. Some of the children were married. Perhaps such a case is hopeless, but there are many in the country who never read any papers or magazines except the farm papers. Such women can be reached only by them. If the department could devote some space to the hygiene and rearing of children it would be fine. After all, they are the farmer's best crop. I read with much interest what has been printed on the subject, and would appreciate more. I have two little chaps of my own, and though they are husky little men I don't feel I know enough about them to rear them properly.

GERTRUDE JACK.

Milk, Eggs and Better Farm Children. Balanced Ration for Humans.

THE farmer goes through his herd, rubs his hands affectionately over the flanks, feels of the skin or inspects with his eye every creature in the long line. He stops—for he sees something wrong in skin or appetite! The diet of the ailing animal is changed.

The farmer goes to his house and finds his child is out of sorts. It is pale, anaemic, listless. It continues to eat the

ENJOYING A SUN BATH.

same food as its father—*but is given a dose of medicine.*

The farmer gives his cows and horses, his calves, pigs and chickens balanced rations. His child eats "just what we do." His cream is sent to the creamery, his skimmed milk is fed to calves and pigs, and his eggs are sold at the store. His calves and pigs flourish, his bank account grows but his child wilts.

Give your child an even chance with the pig, and see his cheeks grow red and feel his little muscles grow firm and elastic. Skimp the pig and give the youngster skimmed milk to drink. Do not scorn skimmed milk. The figures in the following table shows what a superior food milk is even when skimmed.

	Protein	Fat	Carb.
Skimmed milk	3.4%	.3%	5.1%
Whole milk	3.3%	4.0%	5.0%

Last Winter I had an unusual chance to see how the country child eats and I know that some parents need to be shocked into having as much solicitation about balanced rations for their children as they now have for calves and pigs and the proper kind of mixed feed to make the hens lay. "They don't like it"—"they won't touch it" is the common defence for depriving the children of milk. "We eat them when they get cheaper"—"we eat them *then* till we get tired of them" is the reason offered for sending all the eggs to the store. Whose fault is it that the children prefer coffee and tea to milk?

I had supper and breakfast with the Browns. At both meals two small boys, pale, listless little fellows, and I ate fried, dried-up meat, potato, pickles, cookies, cake, pie and doughnuts. Together we drank poor coffee and tea. For breakfast we had a tablespoonful of one of the most expensive and least nutritious ready-to-eat cereals with an infinitesimal amount of milk. In the pantry were big bowls of eggs *ready to go to the store.* In the separator room were 300 quarts of milk, but only two quarts a day and no cream came to the house. Meantime the blood of those little shavers was simply crying out for more red corpuscles which eggs will build better than anything else, and their bones and tissues were soft and flabby for want of lime, while milk contains more lime than saturated lime water.

Eggs should be used by the whole family every day, but if you honestly find that you can't afford them every day for yourselves, try to give at least one to your child. Rob the storekeeper and save out a few eggs for your child. It is poor economy to sell eggs and milk and buy meat. If you raise your own meat it is poor economy to feed it three times a day to yourself, for the body is burdened to get rid of harmful products which meat forms. If too much meat is bad for grown-ups think of the effect on your child.

Mrs. Brown said to me: "I don't like Winter. It seems as if we have so much more sickness then. Frank (the 16-year-old son) has had to lay off work for a couple of weeks on account of boils and the other two children have been sick off and on all Winter." She saw no connection between Winter diet and boils, Summer diet and health.

Vegetables and fruit are of the greatest importance in the development of children, and should be eaten freely by everyone. It would be better to bring the child up on a strictly vegetarian diet than on the present one of so much meat. If we limit the important sources of iron (fruit and vegetables) we cause a sluggish blood formation and an entire absence of reserve iron such as is usually found in healthy individuals. They neutralize acids and other harmful substances in the blood and tissues.

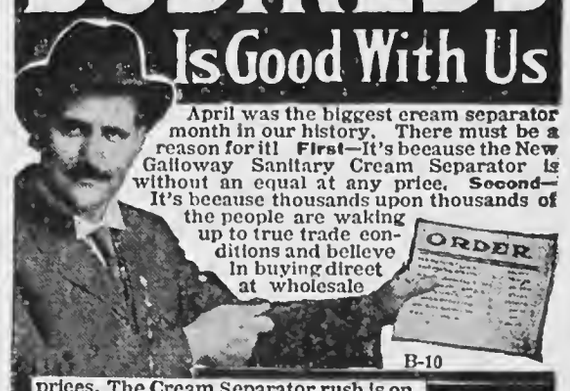
It is just as easy to plant the seeds of good health as of sickness, if you will take the pains to learn how. Usually the three meals a day are planned with entire reference to the *man's* need. They consist of meat, potatoes, bread, butter, pickles, pie, cake, cookies, doughnuts, coffee or tea. These things may be all right for the farmer and the woodsman, but they are *not all right for the child.*

The sweets for children at the end of the meal are, properly, jams, stewed fruits, cookies, puddings made of milk and eggs or fruit jellies. Children should never have pies or doughnuts, which contain too much cooked fat, neither should they have any fried foods. The child will never miss what it has never had. It is the mistaken kindness of giving "just a little taste" of grown-up's food that makes the mischief leading to abnormal cravings. You are kind to your child only if you feed him so that he will be well while he is growing and after he is grown.

Cream, milk and eggs are the best muscle building foods for children. Pork, pie, doughnuts, tea and coffee are the worst things which your child can have.

ANNETTE CHASE DIMOCK.

BUSINESS Is Good With Us



April was the biggest cream separator month in our history. There must be a reason for it! First—It's because the New Galloway Sanitary Cream Separator is without an equal at any price. Second—It's because thousands upon thousands of the people are waking up to true trade conditions and believe in buying direct at wholesale prices. The Cream Separator rush is on. Orders are coming in thicker and faster than ever. Write me today. This is your opportunity to get the best, neatest designed, closest skimming, easiest running separator made at a price that has competition on the run.

Galloway's New Credit Plan makes it easy to own a separator. Order now. Pay later. I'll trust you. Five different selling plans. The New Galloway Sanitary is a mechanical masterpiece, dust proof, enclosed gears, runs in a constant bath of oil, sold on 30 to 90 days trial. I'll back it against any make at any price and let you be the judge whether it is up to claims.

HOT WEATHER the ideal time to use a DE LAVAL SEPARATOR

THERE IS NO TIME WHEN the use of the De Laval Cream Separator is so indispensable to the profitable production of cream or butter as during the hot weather of midsummer.

THE USE OF THE SEPARATOR at this season usually means the difference between a profit and a loss in dairying. It accomplishes a great saving of butter-fat that goes to waste with any other method of separation and enables the production of a higher quality of cream than is otherwise possible.

MOREOVER WITH A DE LAVAL the advantages over other cream separators are greatest at this season because the separation is more complete and the cream heavier and more even in texture. De Laval machines turn more easily and the capacity is greater, doing the work more quickly.

IF YOU HAVEN'T A SEPARATOR you can scarcely afford to put off any longer the purchase of a De Laval, or if you have a separator which is not doing satisfactory work there is no better time to discard it in favor of a De Laval, first trying the machines side by side for your own satisfaction, which every De Laval agent will be glad to give you the opportunity to do.

See the nearest De Laval agent AT ONCE, or if you do not know him write direct to nearest office below for any desired information

The De Laval Separator Co., 165 Broadway, New York, 29 E. Madison St., Chicago

50,000 BRANCHES AND LOCAL AGENCIES THE WORLD OVER

The Henyard.

THE EGG-LAYING CONTEST.

THE report for the month of June shows an egg production of 13,983 during the month. The largest number laid by any one pen was 249, by the English White Leghorns. This is an average of nearly 25 eggs by each pullet. One of these pullets laid 28, and two laid 27 each. Chas. N. St. John's White Leghorns laid 238, taking second place in the monthly score, and P. G. Platt's pen of same breed are third, with 236 to their credit. Geo. A. Cosgrove's pen laid 235. Thos. W. Moore's pen laid 227, and Branford Farm's pen laid 227. Glenview Poultry Farm's pen laid 225, and 12 other pens of White Leghorns laid 200 or over. Outside of White Leghorns there were only two pens that reached 200. One was the White Wyandottes of Merrythought Farm, 202; and the S. C. Reds of A. B. Brundage, which laid 211.

The report for the thirty-sixth week shows an output of 3,076, which is a drop of 76 eggs from the score of the previous week. The best laying months of the year are past, and we must expect a gradual decrease in the number of eggs laid. White Leghorns continue to make all the high scores; the highest for this week is 57, by P. G. Platt's pen. Chas. Heigl's pen from Ohio are second with a score of 55, and the English pen are third with a record of 54. Thos. W. Moore's pen tie with the "sour milk" pen from Storrs Agricultural Station, with scores of 53 each.

Outside of the Leghorns A. A. Hall's Buff Plymouth Rocks laid 51, tieing with C. H. Savage's, and Geo. A. Cosgrove's White Leghorns. Barron's White Wyandottes are now only 18 eggs ahead of pen number 42, the "sour milk" pen of White Leghorns from Storr's Agricultural Station; but as these are not in the contest for prizes, the real opponent is Francis T. Lincoln's Leghorns, which are now 33 eggs behind Barron's Wyandottes. But steadily climbing up is pen number 68; Barron's White Leghorns. As late as March they were in the tenth place, now they are fourth. But they are 124 eggs behind Lincoln's and in the 15 weeks left would have to gain over eight eggs a week to catch up, and this is too much to expect. As it looks now Connecticut is the winner. The week's record follows:

GEO. A. COSGROVE.

Eggs Versus Feathers.

IT would be decidedly interesting if we could take the winning birds of the utility breeds, at all our great poultry shows and enter them directly from the showroom into the egg-laying contests. But the fanciers, as a rule, haven't got the nerve to try it. Occasionally one does put in a pen, not of his show birds particularly, but of the breed he is interested in, and usually the showing they make is not one to be very proud of. Some years ago, when I was breeding White Wyandottes, I had in the flock an exceptionally good layer. From the Wyandotte Standard she was a disgrace to the yard; undersized, with a comb something like a Light Brahma, too long-bodied for a Wyandotte, she was so different from the general average of the flock that I could not use her to breed from at all. She laid all Summer, was broody for a few days, then began laying again, and kept it up until late in the Fall; she was the last one to molt and in 40 years' experience I never knew a hen to molt and get a new set of feathers so quickly. I did not set down dates, so have no means of knowing the exact length of time, but it did not seem to me that she took half the usual time. I remember with what surprise I saw her with a red face on the nest again laying. The point I want to make is this. Here was the very best hen I had raised in years; from the utility standpoint the most valuable hen on my farm; but I was so bound up in the theory that a Wyandotte must conform to the "Standard" and that no bird was fit to use as a breeder unless it did so conform, that I sold this best hen to a peddler to be killed for market. Breeding "Wyandottes," of course I must furnish eggs that would produce birds as close as possible to the Wyandotte standard.

The fanciers themselves are beginning to see the unwisdom of some of the standard requirements, and are not insisting on such shortness of body as formerly. I understand that there is a movement on foot now to change the standard in this respect. The effect of breeding to standard was well illustrated by the experience of Mr. N. J. of Connecticut. At the Springfield, Mass., Poultry Show he won first premium for the best pen of White Wyandottes. I was there and saw them, and they certainly were beauties, very short-bodied, and up to the "standard" in every way. I met Mr. J. in Hartford two years afterward and asked him how his Wyandottes were doing?

"Haven't got any," he replied. "I bred 'em just as the judges wanted them, but they wouldn't lay, and what eggs they did lay wouldn't hatch, so I got rid of the whole bunch." Mr. J.'s experience was an extreme one, but it clearly shows that the tendency of the fancier is to make a fad of some unimportant feature and run that to an extreme, regardless of its effect on the utility qualities of the fowl. Birds are disqualified by the "standard" for trifles that do not in any way affect their usefulness, and that should be cut as a defect, instead of disqualifying the fowl. The egg-laying contests are doing much to educate the American people away from the idea that any particular breed is always better for egg production than any other. We are learning that exceptional individuals exist in many breeds, and that what the commercial egg producers want is to select and breed from those that show the best performance, whether they conform to some arbitrary standard or not. This must be done with judgment, or results will not be what one might expect.

GEO. A. COSGROVE.

Loss of Feathers.

I HAVE a couple of R. I. Red hens that have lost the feathers on their heads, and a few Plymouth Rocks that have lost the feathers on the front of the neck. It does not affect the white hens. I have greased their heads with lard and kerosene but it does not seem to make any difference. Can you advise me what to do? I do not think it is mites, as the house is clean. E. S.

New York.

The mite which causes the loss of feathers from a fowl's head and neck is not the red mite found about the perches and nests, but another variety which burrows in the skin at the base of the feathers and remains continuously upon the fowl. If ordinary grease will not destroy this pest, add one-fourth its bulk of "blue ointment," obtainable at any drug store, to the lard or other grease used and rub in well over the affected spots. You will, of course, have to give new feathers time to grow before the appearance of the fowl is improved. M. B. D.

DEPENDABLE POWER FOR LIGHT AND WATER

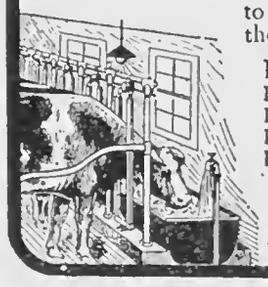
WHILE other work *might* wait, the power for light and water must always be "on the job" when wanted. You can't afford to risk possible trouble or delay at a critical time. You need an engine that you can "bank on" every minute. Such dependability as this—such absolute reliability—is characteristic of

The Lauson Frost King

Gasoline and Oil Engines

No Cranking.—Engine starts on magneto, without turning over. Special design and exclusive Lauson features cut down fuel expense. *Perfect Balance*—Engine stands quiet even under full load. Every part accurately ground and fitted. The Lauson Frost King is known to thousands as the *standard* of farm engine quality. Special features of the Lauson Frost King put it in a class by itself. *No Batteries*—all batteries and expense incidental thereto are eliminated by the Sumter Gear-Driven Magneto.

9 *Guaranteed*—We absolutely guarantee Lauson Frost King Engines to make good on every claim we make for them. Also as to workmanship and material.



Write for New Engine Book

Illustrates and describes all styles of Lauson Frost King Engines from 2 to 50 H. P.—Portable, Semi-Portable and Stationary. In writing us state size engine you need.

PUBLISHER'S DESK

I am pleased to notice your exposure of the Cloverdale Farm Co., Ransomville, N. Y. They are the ones who deceived me last Winter and Spring and from whom I had so much difficulty in getting the clover ordered. G. P.
Massachusetts.

The above reference to the experience of another subscriber in Publisher's Desk of July 11 issue only emphasizes the necessity for the word of warning to our people. Anyone who contemplates any business transactions with the Cloverdale Farm Co. will do well to look up the record of Mr. E. E. Cooley, whom we understand to be the active member of this company, at Frenchtown, N. J., where he was engaged in the poultry business for a number of years.

In September, 1908, I took an installment contract from Wood, Harmon & Company, 261 Broadway, New York City, for a lot in Midwood Manor (a new subdivision in Brooklyn) at $1,635. I understood that in case of any emergency that I could not continue my payments, the money actually paid in without interest would be returned. After paying on my contract about $483 I was unable to continue on account of financial difficulties, and upon asking for a return of part of my money, I was put off from time to time, saying that they would carry my account and I need not be uneasy, or words to that effect. Finally last year they wanted all back payments at once or I would lose all. I was unable to pay same and petitioned the head of the firm for the return of some of my hard-earned money (if only half of what I paid them) but could get nothing from them. I would be very very thankful if you could get any return for me from said real estate firm if only half of what I paid them. P. C. H.

We took this complaint up with Wood, Harmon & Company; but they refuse to make any adjustment. They say the expense of selling the lot, and city taxes equal the amount paid on the contract. As to the purchaser's understanding that the money would be returned in case of his inability to keep up the payments, there seems to be nothing in writing to this effect and no claims on the part of the buyer that there was, but he quotes conversation with the agent to show definite verbal agreement to this effect. The company, however, prefers to accept the assurances of their agent to the effect that no such promise was made. So there you are. The buyer loses his $483.

We know nothing of the verbal representations made to induce this man to agree to purchase this lot, but we are satisfied that he did not enter the contract with a proper understanding of the situation or with a prudent estimate of the value of the property. We believe he was deceived by some influence. Some years ago, a Virginia subscriber asked our advice about the purchase of a Brooklyn lot promoted by Wood, Harmon & Company. We told him that such property is bought up in acreage plots, that streets are then laid out, and the lots are sold on the installment plan to small investors at prices very much in advance of our estimate of their value. Frequently such lots are abandoned after a few payments have been made, and the investor loses his money. Acres of such lots are sold every year on Long Island for taxes. Finally we told our Virginia subscriber to send $10 to a reliable real estate appraiser, if he wanted to know in advance how much he would be stuck on the purchase. The company felt very much grieved at the time that we should refer to the transaction in that language. For our part we consider the language mild. A candid expression of our opinion of these real estate transactions would probably include some words that ought not to appear in print.

Referring to Dr. Ulman's article on page 246 of your issue of February 14, 1914, and your comment on same, I would very much like to become a charter member of the Society for Suppressing Dishonesty and Frauds. This society will have a greater work before it than can be realized at first glance. In this connection I am reminded of that splendid editorial which appeared in your paper a few months ago, in which you gave your views and reasons for refusing advertisements for tobacco and cigars, even from reliable firms, for ethical reasons. When the greater part of reliable publications get to the point where you are in this respect the world will see a radical change in physical, mental and moral state of our lives. What an almost unbelievable gulf there exists between your position and the general run of literature. In the Y. M. C. A. club houses here on the Isthmus, and everywhere else for that matter, the library tables are covered with daily papers, weekly and monthly magazines, nearly every one of them with their full quota of tobacco, whiskey and patent medicine advertisements. This is one of the worst influences in existence today that helps towards making the use of tobacco and strong drinks popular, and leads young men, and I may as well include women, to drink and consequent ruin. The work before this society will not be accomplished in a day or a year. We are in for a prolonged siege, a campaign that must be planned and stuck to with the determination that characterized the siege of Troy.

Largely because my eyes have been opened by reading THE R. N.-Y. I have discontinued subscriptions to other publications I used to take. At present I have a monthly magazine for which I subscribed for a period of 10 years, and I am positively ashamed to have it in the house. It carries no whiskey ads, but such frauds as Sanatogen occupy whole pages, and by my paying for my subscription and patronizing that magazine I am made a partner in charging the credulous $2 for five cents worth of cottage cheese.

Now a final word about the Society for the Suppression of Dishonesty and Fraud. THE R. N.-Y. is entirely too modest. One hundred members!! What? If this society can't show a membership of ten thousand within three months I will lose faith in humanity. I hereby cast my vote for Dr. Ulman as the first president of the Society for the Suppression of Dishonesty and Frauds. If Dr. Ulman is a practicing physician, I am afraid he will, in course of time, have to give up his practice, because there will be so much work in his new position that he will not have time for anything else.
Canal Zone. J. J.

It was not our intention to limit the society to 100 members. We promised that we would help organize the society when 100 readers signified a purpose to become charter members. It will be a distinction to be one of the first hundred to found a society which ultimately in some form will include 80 per cent. of the people of the Western Hemisphere. We made the suggestion on the impulse of the moment. The responses have been prompt and enthusiastic. The list is growing, but the 100 are not yet filed. Where are the women? The membership so far are men. We believe the women are even more interested in this than the men.

I had the same experience as F. F. H. and J. D. S.. I sent the Cluthes nine dollars for a truss on trial. When I wrote them that I could not wear it and asked for my money back they wrote me a curt letter and refused to pay the money. T. C.
Ohio.

It is quite likely that many others had the same experience. From the language of the advertisements, we would expect that a purchaser could return the Cluthe's truss and get the money returned; but such seems not to be the case. We do not know whether the money could be recovered on suit or not. It does not matter. Anyone would rather lose the money than attempt to recover it through a suit at law. If everyone who had this experience complained to the Post Office Department, the abuse would probably be corrected.

Nearly a year ago I sent White Cross Anti Liquor Society, Kansas City, Mo., $7.50 for anti-liquor treatment. They advertised to guarantee a cure or refund the money. The medicine did no good and I have been unable to get my money back as promised. L. G.
New York.

We wrote the alleged society in the subscriber's behalf and it admitted that the remedy was sold on conditions that if it did not effect a cure the money would be refunded. Instead of refunding the money as agreed the society sent two more treatments as an offset to the refund guarantee, claiming they did so with consent of the customer, and therefore consider all obligation cancelled. The subscriber denies having agreed to the arrangement. However, this may be; we know that this plan is resorted to by many medicine advertisers to avoid making the refund as agreed at the time of sale and a few advertisers in other lines seem to be following the lead of the patent medicine men. It is important to understand that the apparently liberal propositions made by this class of advertisers in cheap publications have a string to them, and that the advertisers have no real intention of ever returning the money under any circumstances. J. J. D.

DAIRY REPORTS.

THE southeastern part of Ohio is the section that we gather cream from and there is a growing interest towards the dairy business in this section. The hilly country throughout this section is more adapted to dairying than to the tilling of the soil. Is there as good an opportunity in the future as in years gone by? I would say yes, better. In regard to the proportion of the cows in our locality that are well bred, or of the improved breed, it would be hard to say, but I judge that not one farmer in 20 has the improved breed. There is where I base the above answer to your question and where I see a greater chance for improvement. In regard to advising young men and women to take up the business of dairying as it stands today, with a fair hope of being successful, I would say yes, I think there are great opportunities in the dairy business. L. D. C.
Ohio.

IN regard to dairying, there is all kinds of stock except purebred. Very few of these are kept. Pastures are very poor and run out and burned out through the dry hot seasons we have had. As to purebred bulls, few farmers are able to own one. There are a few Holstein purebreds, but only the rich farmers can afford them. Prices of farm produce are very good. Butter 30 cents; cheese 16 to 18. Bought a small farm of 80 acres in fair cultivation; keep 10 cows, grade Jersey, Guernsey and black and white. Am hoping to improve them if I get able.
New York. O. E.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending July 17, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914	1913
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.51 and $1.41 for B and C. Hotels and restaurants using two to three cans per day are paying 4½ to five cents per quart.

BUTTER.

Prices have been both up and down during the week, closing one cent higher on the top grades, which form a much smaller percentage of the receipts than usual. Lots scoring above 93 are scarce. From 91 down is an abundance at prices favoring buyers.

Creamery, extra, lb	27½	@	28
Good to Choice	23	@	26
Lower Grades	20	@	22
State Dairy, best	25	@	26
Common to Good	18	@	23
Factory	16	@	20
Packing Stock	16	@	19

Elgin, Ill., butter market 27½ cents.
Philadelphia, western creamery, 28½ cents.

CHEESE.

There has been an advance of one-half cent on the better grades of whole milk. Business is dull and speculative buying scarce. The tone of the market indicates a drop rather than further advances or even a holding of the present fractional premium over previous weeks.

Whole Milk, fresh, specials	14¾	@	15
Average fancy	14¼	@	14½
Under grades	10½	@	13¾
Daisies	15	@	15¼
Skims, specials	11¼	@	11½
Good to choice	10	@	11
Poor to fair	5	@	9½

EGGS.

A wide price range is needed to cover current business, though the top figure given, 29 cents, represents but a small volume of sales, mainly because those qualities are scarce. Ungraded lots, averaging fairly good, bring 17 to 20 cents. Grades under this are in considerable surplus.

White, choice to fancy, large	28	@	29
Common to good	20	@	25
Mixed colors, best	25	@	26
Common to good	17	@	20
Western fresh, white	21	@	22
Lower grades	15	@	18

FRESH FRUITS.

Most of the new apples offered are unattractive and selling at low figures. Choice hand-picked Astrachan and similar early varieties sell readily at the top figures quoted. Le Conte pears selling well, mainly on the basis of $3 per barrel. A few Southern Elberta peaches have sold up to $3 per crate, but most other varieties running under $2, many down to $1.25. Strawberries are practically gone, only a few Western New York arriving. Bush fruits considerably out of condition because of rain and muggy weather.

VEGETABLES.

Potatoes in considerably increased supply and 50 to 75 cents per barrel lower, $3 being the top for best Long Island. Onion market dull. Choice Jersey corn brings $2 or more per 100, small or poorly filled ears $1 to 75 cents. Cabbage plentiful and mainly low. The recent disastrous prices of lettuce have slackened shipments, so that there has been some price improvement. Peas and string beans very low.

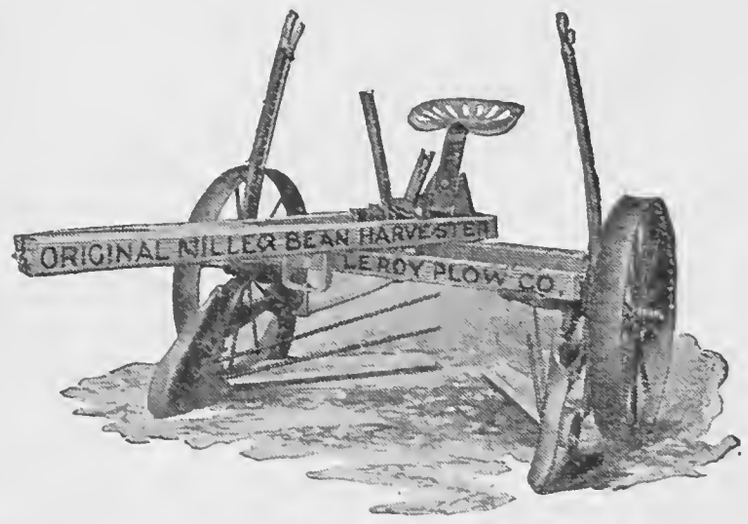
These Are the Reasons Why All Farmers Like the Only Original Miller Bean Harvester

Every farmer likes the **ORIGINAL MILLER BEAN HARVESTER** because it handles so easily, is strong, steady, durable, reliable and has just the right weight to hold to the ground and do the best work.



The wheels are made of high grade steel with 4-inch concave tires so that they will not slide or sink in the soft dirt. Both shanks are heavy, reinforced with a crosspiece to eliminate breakage. All shares are of the very best grade 5-16 inch steel and with re-sharpening will last several seasons.

The **ORIGINAL MILLER** is the best and most popular bean harvester and is guaranteed to do better work than any other bean harvester made. All others similar are inferior imitations. When you buy, insist upon the ORIGINAL and you will get the best.

HUMOROUS

"Is a ventriloqu[illegible] person who throws his voice?" [illegible]d Mr. Lobrow. "So to speak." "W[illegible]e've got one next door. She hasn't [illegible]n it yet, but she is giving it a ter[illegible] struggle."—Washington Star.

"In choosing his men," said the Sabbath school superintendent, "Gideon did not select those who laid aside their arms and thr[illegible]w themselves down to drink; he took those who watched with one eye and drank with the other."—Philadelphia Ledger.

"How are you going to explain your vote to the folks out home?" "I'm not going to explain," replied Senator Sorghum. "The people out my way are all fond of music. I'm going to have a rally and announce myself for a big speech. Then I'll hire a band to drown me out."—Washington Star.

"Well! Well!" said the farmer as he rushed to the gate, his hand extended and his face wreathed in smiles: "I'm glad to see you! Come right up on the porch and rest yourself in the rocker." "Thank you," replied the visitor. "I came around to see about Summer board." "Summer board! Why didn't you say so quick instead o' raisin' my hopes! I thought mebbe you was lookin' for work."—Washington Star.

Billy (who is putting in a long Sunday afternoon): "Let's play auto with the chairs, mummy, and you take a ride with me!" Mother (with an eye to the uplift): "I guess not, dear; I really don't approve of pleasure rides on Sunday." Billy (after a moment of earnest thought): "But this isn't a pleasure ride. We'll play I'm taking you to see a moving picture show of scenes from the Bible."—Life.

A presbyterian preacher stopped at a Kentucky mountain cabin one day, where a gaunt, ragged woman leaned on the dilapidated gate. "Where is your husband today?" inquired the preacher. "Out huntin'." "Any Presbyterians around here?" "Wal, now, thet I don't know, stranger, but the hide of every kind of animal thet my husband ever killed is tacked up yander on the back of the smoke-house. You might step thar an' look."—Credit Lost.

This open letter "To John," in the "personal" column of a weekly paper: "To John—If you'll come back home, John, I promise not to run for office—if I git a chanst—and not to search your pockets when you come home, as usual, in your cups; neither to find fault with you more'n what's necessary for your own good, and not to throw up to you any more 'bout me havin' to pay for the marriage license; and not to tell you my family is better'n your'n—though Lord knows it IS. So I close, hoping these few lines will find you on your way home, where any man with a grain o' common sense orter be."—Atlanta Constitution.

The second-grade teacher was a young, timid girl. Among her new class was Tommy, who, for naughty deeds, had been many times spanked by his first-grade teacher. "Send him to me any time you want him spanked," said the latter, "I can manage him.' One morning about a week later, Tommy appeared at the first-grade teacher's door. She dropped her work, seized him by the arm, dragged him to the dressing-room, turned him over her knee and did her duty. When she had finished she said: "Well, Tommy, what have you to say?" "Please, Miss, my teacher wants the scissors."—National Monthly.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. LXXIII. No. 4266. NEW YORK, AUGUST 1, 1914. WEEKLY $1.00 PER YEAR.

COST OF APPLE PRODUCTION.

Spraying and Labor.

WILL some of your experts tell us the cost of growing an apple orchard to bearing age; cost of handling the crop and other figures regarding labor, tenant system, etc. We would like figures from various parts of the country if possible.

B. M.

VARIATIONS IN COST.—Of course, your correspondent understands that the cost of apple production, including all the items of labor, as well as material costs, varies according to conditions. The chief factors influencing cost are: The efficiency of labor, the rate per hour, the size of the farm and the orchard, and the relationship of the orchard enterprise to other farm enterprises, whether the orchard is cultivated or kept in sod, the number of sprayings, the age and size of the trees, etc. With these variations in cost in mind, I will give some actual figures of costs on one orchard. The inquirer must understand that these costs may not be his costs; they will simply give him an idea of what these costs are likely to be under normal conditions in a well-cared-for old orchard in Western New York.

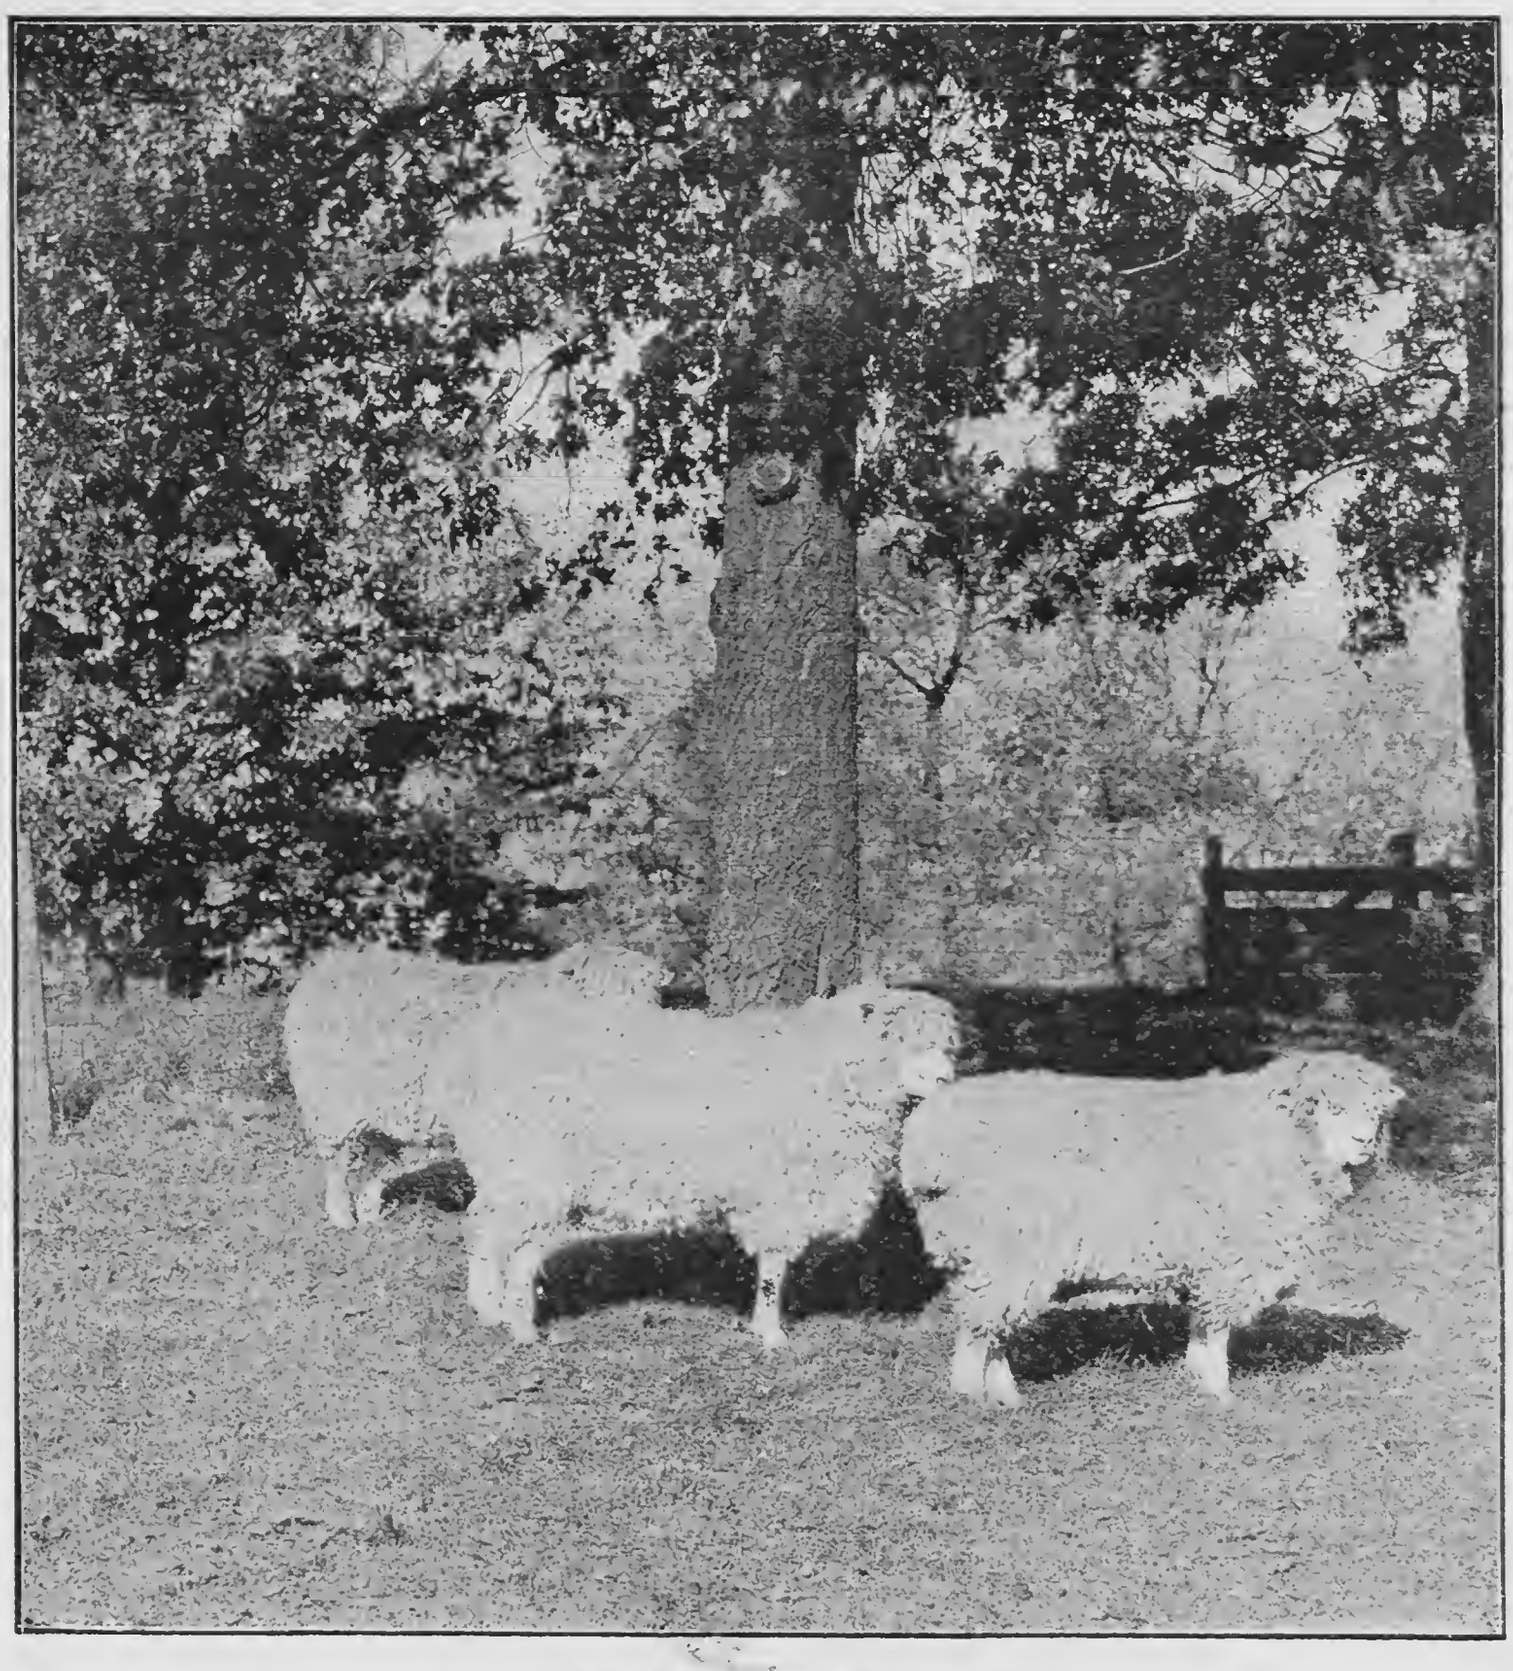
FIVE YEARS' RECORDS.—Table on next page shows five years of very accurate cost records on a six-acre apple orchard containing 230 trees. Part of this orchard is 40 years old and the rest nearly 60. The varieties are: Baldwin, Tompkins County King, and Twenty-Ounce. Some pruning is done every year. The orchard is plowed and thoroughly cultivated three years out of four. A cover crop of clover and buckwheat is used about every other year. It is usually sprayed with a power sprayer three times during the season. About one-quarter of the orchard is manured each year. The labor costs are given in man and horse hours and fractions for each operation. Man labor costs us 20 cents an hour, horse labor 15 cents an hour.

In answer to your request for information as to the variation in yield and price of fruit over a period of years, I give you figures for 12 years on the above orchard in barrel yield per acre and prices per barrel. In the total price per barrel is included value of drop apples and culls. This is also given on the following page, with the other table referred to.

CONTRACTS FOR RENTING.—The inquirer will readily understand that the terms of renting orchards must necessarily be based on the relationship of the orchard to the whole farm enterprise, and on the age, variety and condition of the trees. In my own case the orchards, which cover 25 acres in all, and which are of various ages, are a part of the general farm enterprise which totals 105 acres in area. After trying several less liberal leases, we have settled down on one which is quite satisfactory to both tenant and owner. In this lease the owner furnishes all the capital, including horses and machinery, and one-half of the materials, such as spraying material and fertilizers. The tenant furnishes all the labor (except such part of the horse labor costs, as are due to interest, depreciation, one-half the feed, etc.), and one-half of the cost of materials. As you will note from the above figures, the total labor costs of producing apples amount to about one-half of the entire cost. This total labor cost, however, includes a part of the horse labor cost which the owner bears. This just about offsets the material costs contributed by the tenant. Assuming that capital and labor are factors of approximately equal importance in apple production, and that they should, therefore, receive the same returns, the above form of lease would seem to be a satisfactory one. In effect, this lease provides for the deduction of all the expenses (including interest) from the returns from the orchard, and dividing the net profits equally.

VALUE OF ORCHARDS.—There are three ways of determining the value of an orchard: (1) What it can be sold for. (2) What it cost to grow the orchard. (3) The amount of money on which the orchard will return a fair rate of interest—six to 10 per cent. I do not believe that any one of these methods can be used exclusively; a combination of them must be employed. What the orchard can be sold for is really the best measure of its true worth, but if the buyer is a wise man he will base his offer for the orchard on the probable returns from the orchard over its probable lifetime. If the seller is a wise man he will fix the selling price at least as high as the cost of the orchard. Somewhere between these two factors the true value lies. Practically an apple orchard of good varieties, *sound trees in their prime,* is worth not less than $300 an acre, and may be worth as high as $800 or possibly $1,000 an acre. In Western New York $500 an acre is a fair valuation for a good orchard. The orchard on which the figures are given above is valued at $275 an acre. Many of the trees are missing and about one-half of them have passed their prime.

SPRAYING MACHINERY.—A 2½ to a 3½ horse-power engine is, in my opinion, the best size for spraying. The smaller size is sufficient to give the power needed, but not sufficient to do many other kinds of farm work for which it is desirable to use an engine. Hence we use a 3½ horse-power engine. The objection to this heavier engine is its weight, which sometimes makes it difficult to get on the land early in the Spring. This is more apt to be a difficulty in spraying peach orchards than apple orchards, however. Personally I like the "outside packed" style of pump, better than others. This is only a personal opinion, however, and not worth much at that, because I have not personally used the other kind. I think there is no doubt but



A BUNCH OF PRIZE-WINNING COTSWOLD SHEEP. FIG. 412.

what the simple swing dasher style of agitator is the best. If properly made so as to go the whole length of the tank and operate close to the bottom, it is very effective.

TYPES OF NOZZLE.—The kind of nozzle to be used depends partly on the time and the purpose of the spraying. A coarser spray may be used with the first spraying on the dormant trees, because there are many branches as well as the trunks of the trees to be covered, and some force to get into all the crevices is desirable. For this work the Bordeaux type of nozzle is, in my opinion, the best. When it comes to spraying on the foliage, however, and particularly in spraying for fungus diseases, the finer spray is much more desirable. If the material is properly strained and the tank is kept closed, there is very little danger of worry and delay from clogging. If a tower is used, as it should be with high trees, the range of these mist sprays is not too limited.

TRUCK AND HOSE.—In most cases it is desirable to have the front wheels of the truck turn under the tank so that short turns can be made at the end of the rows. In practice we use an ordinary wagon truck, with the spraying tank mounted high enough so that the wheels turn under easily. We use one line of hose from the tower or top of the tank, and one line from the ground. A 3½ horse-power engine would carry a third line of hose, but I do not think this necessary or practicable in a small orchard on a general farm. We use batteries instead of magnetos. Where there are only a few trees, as 30 to 50, if labor is plentiful and capital scarce, a "one-horse one-man" spraying outfit might be practicable. For any proposition involving 150 trees or more, I do not think that such a small outfit would be practicable. It would increase rather than decrease the cost of spraying. Spraying is not as troublesome and expensive as your correspondent has been led to believe. Before a man has done any of this work, it looks difficult and expensive. When he really gets at the job, if he tackles it just as he would any other important and worth while piece of business, he will find that it can be handled just as easily.

M. C. BURRITT.

A GOOD HAYRACK.—Fig. 413 shows the arrangement of a hayrack used by Ernest Hoke, of New York. With this rack on the wagon and a good hay loader at work a load can be put on in 20 minutes. There can be no sliding off or tipping over when a rack of this kind is used.

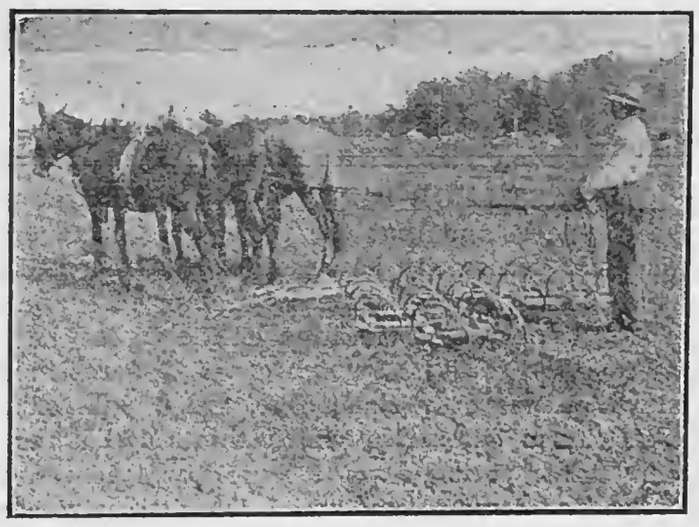
THE real test of farm management comes now when the crops are young, and a dozen things crowd at once.

FERTILIZING FOR A SECOND GRASS CROP.

I HEARD some time ago of a person up in Connecticut who was top-dressing his grass field after he had got his first crop, and by so doing obtained a very good second crop. I have had such very good success by the use of the nitrate of soda on my Timothy sod that I am tempted to try an experiment on my new grass field, where I just cut a very light crop owing to the dry weather. Since the recent rains the grass has revived wonderfully, and I have a notion of making an experiment by using a ton of fertilizer at the rate of say about 500 pounds to the acre. Have you had an experience along this line? If so, what has it been and, if not, what would you think of the idea? I don't think we half study the needs of the soil for the growing of our grass crops, especially in comparison with the way we study the needs for our potato crops, and after everything is said and done, don't we often get as large returns from a good field of grass as we do from many of the crops of potatoes?

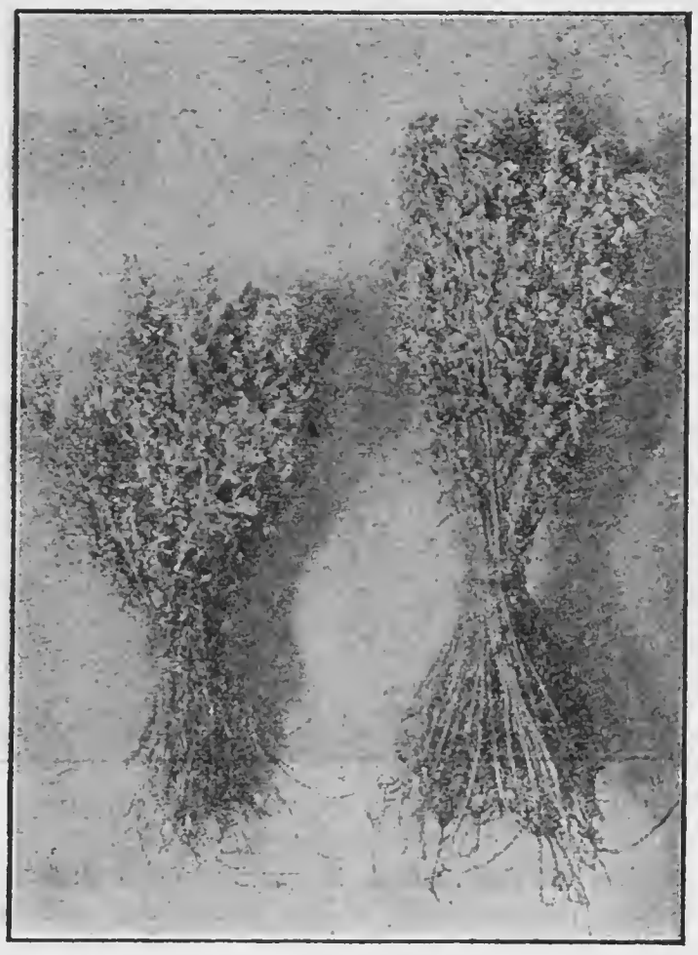
Grenloch, N. J. F. H. B.

Many experiments have been made with a top-dressing of nitrate of soda after the first cutting, in order to increase the second crop. The outcome



CULTIVATING AN ALFALFA FIELD. FIG. 413.

depends largely upon the season. It often happens that the grass is fertilized quite heavily in the early Spring with a mixture containing nitrogen, potash and phosphoric acid. There follows a dry April and May so that the grass crop is light. Then in July rains will start and continue for the Summer, as seems likely to be the case this year. In such a season and under these conditions the application of nitrate of soda alone will usually pay well. A quick growth of grass is started, and as potash and phosphoric acid were used freely in the Spring it is unnecessary to use more of these elements for the second crop. The hay grown by this use of nitrate of soda or sulphate of ammonia is usually of extra feeding value, and under the conditions here mentioned an application of nitrogen will pay well. It is a mistake, however, to use nitrate alone for such a crop, unless we are sure that the soil contains an abundance of potash and phosphoric acid. If there is any doubt whatever on that point, it would be far better to use more of a complete fertilizer containing all three elements of plant food. For this purpose it would be more economical to use all the nitrogen in soluble



UNLIMED AND LIMED ALFALFA. FIG. 414.

form, such as nitrate of soda or sulphate of ammonia, using acid phosphate and muriate of potash in addition. Under the conditions stated above such an application will undoubtedly pay, and this plan will be followed quite freely this year by a good many farmers who find their first crop greatly reduced by the drought. There is no question about the need of studying the soil conditions best adapted to grass culture. One of the first things to be understood in this connection is the fact that Timothy and clover must have neutral or alkaline soil conditions. Neither crop will do well in a soil that is acid or badly lacking in lime. In fact, thorough liming is the foundation to be laid in the production of such crops as Timothy, clover and Alfalfa. Red-top will make a fair growth on a soil that is quite acid, but Timothy must have an alkaline soil to do its best.

Another point to be observed in grass culture is the fact that the growth is made very rapidly, and the grass must therefore have a constant and available supply of nitrogen, which is the plant food element most responsible for growth. This means that the nitrogen should be supplied in a quickly available form, and not in organic forms, which require warm weather and considerable time to become available. On some of the famous English meadows the liquid manure from tanks or manure pits is sprinkled over the fields after the first cutting. This liquid contains nitrogen in a promptly available form, and such an application is not unlike the use of nitrate of soda or sulphate of ammonia, driving the grass into quick growth and giving a good crop of suitable hay. The soil also contains an abundance of both potash and phosphoric acid. A crop of grass forced into a rank and tender growth by nitrate of soda alone, and on a soil lacking in the other elements, would not be satisfactory either in its appearance or in its feeding quality.

QUESTIONS ABOUT MOON AND PHOSPHATE

IS it right to plant root crops by the old moon and top ground crops by the new moon? This is an old saying carried forward. I have never read anything about it in any paper. Does phosphate weaken the ground by regular use, so that you have to add more each year? All my crops are for garden purposes. Would like to use phosphate because it will not have so many weeds. H. S.

Wallkill, N. Y.

As to this moon proposition, it is right to plant root crops or top crops either when the soil is in good condition, and when danger of frost is past, whether the moon is old or young. We have frequently tried to explain this matter. So far as we can learn, there are no scientific facts to back up either side of the problem. We know some very good farmers who plant by the moon, either old or young, and they claim that this moon planting is responsible for their success. On the other hand there are just as good farmers who say there is nothing whatever to this moon planting. They put in their crops when they get the soil ready, regardless of the moon, and as they are just as good farmers, and get just as good results as the moon men, there seems to be no way of figuring the moon's influence. Personally we pay no attention whatever to the condition of the moon in planting, and we do not believe it has any influence upon the growth of crops. It has often been said that our scientific people ought to take this matter up and give it a test, but there are so many conditions connected with the soil and climate, and other particulars at the time of planting, that we can see no way in which the influence of the moon could be fairly compared. For instance, if one phase of the moon gave a soil plenty of moisture, while the other phase of the moon gave it a very dry time, there would be no way of making a fair comparison, while another year might see the exact reverse of these weather conditions.

We hardly know what you mean by suggesting that a phosphate will "weaken the ground." We presume by phosphate you mean a complete fertilizer containing nitrogen phosphoric acid, and potash. This would not weaken the ground by regular use, since it supplies the plant food which your crops require, and if the soil is poor and lacking in available plant food, it will be necessary to add something of the kind each year if you expect to produce crops. On some kinds of soils the use of a fertilizer alone year after year will not give the best of results, since the fertilizer does not add any organic matter or humus to the soil, and this humus is necessary in order to keep the soil in good condition. Where you use stable manure this organic matter is added, but the fertilizer used alone with the crops taken away year after year, and nothing added in the way of organic matter, would reduce the ability of that soil to hold moisture, or give its best returns. This would not mean that the phosphate had weakened the soil at all. It would mean that the soil had grown hard, and dried out too fast, so that the plants could not get water or a good chance to grow. If you use fertilizer, year after year, and also grow some "cover crops" like rye or clover, and plow it under, the soil will not "weaken" but will be kept up as well as with stable manure.

A PERMANENT TIMOTHY MEADOW.

The "Clark" System Once More.

PART II.

THE SEED BED.—If you can stay by this work to the end, September 1 will find your field as fine and loose as an ash bed. It will be full of pieces of dead roots where the disks have chopped them up. In some cases, particularly where quack grass abounds, it is necessary to rake off these roots to clear the land. We are so friendly to cover crops and humus that on general principles we would use such roots for manure or mulch. Quack grass has so many lives, however, that it will be safer to burn its roots. Not one field in 50 has a true grade or a smooth surface. There are little hollows or depressions in which the water will stand, and Timothy is neither a swimmer nor a duck. If you leave these hollows the grass will be killed out and trash will crowd in. During the last of August Clark went over his fields with a light board scraper filling in the little hollows. Then he used a light straight-tooth harrow to rake over the surface and level it for the seed. The Acme harrow, followed by a plank or brush drag, will do this work well so that by early September the ground is fit for the seed.

MODIFICATIONS.—That was the Clark method of preparing land for seeding. It did the business and the fields thus prepared gave from four to six tons of hay to the acre and kept this yield up, with good feeding for eight or 10 years! Few farmers can afford to fit land in this way, and not many would have the faith to stay by the work with bull-dog tenacity until the soil was fit. The best that most of us can do is to come as near to it as we can. A farmer with only one team or three horses will find a dozen jobs for them in late Summer, at haying, cultivating, or marketing crops and he cannot hope to work any large area 15 or 20 times over. Our experience is that he would be better off to take half the usual area and work it twice as much before seeding as he could the entire space. There can be no question about the effect of this intense culture on the yield of grass. Notice what happens when you sow grass seed on an onion or a potato field. These crops are well fed and we are obliged to keep them clean in order to obtain a yield. The grass which follows always shows the result of this feeding and cultivation. We have found that one disking or plowing followed by five or six workings with spring-tooth or Cutaway gives us a good seed bed. We would rather use the Cutaway to begin with but if it is not possible to carry out the Clark plan, plow deep and cover the furrows well and work all that is possible with a Cutaway going as deep into the ground as the horses can handle the job.

WHITE LEGHORNS "EATING OUT OF YOUR HAND." FIG. 415.

USE OF LIME.—At the time Clark made his experiments the modern facts regarding lime were not popularly known. Clark advocated occasional dressings with lime on the grass sod. We now understand that this is not good practice. In many cases the lime does not work down into the soil. We have known it to form a crust or mortar near the surface—out of the reach of the grass roots. The proper time for liming is when the soil is first turned over. The thorough working by the harrow mixes the lime all through the upper soil. That is just what is needed so that the upper soil may all be acted upon. Slaked lime is better for this purpose than ground limestone, for it gives a quicker action and will help to destroy the old weeds and grass which we are trying to clean out. Timothy must have a neutral or alkaline soil in which to make a quick start and a rapid growth. Thus lime and available fertilizers should be used at seeding. In trying to start a permanent meadow anywhere at the East we should assume that the soil needs lime (the crop does anywhere) and use at least one ton of slaked lime to the acre after plowing or disking the land.

FEEDING THE CROP.—Thus far we have tried to tell how to get the grass plants started so they will be as permanent as a peach orchard. Anyone who has grown peaches knows he may get the trees started if he works right but they will not keep on bearing year after year unless they are fed on plant food which they can take care of, and utilize at once. Consider how rapidly a crop of Timothy must grow. On April 15 in New England it is just turning a dark green where the snow lingered, yet by July 4 it should be cut for hay. This means lively growing and the plant food should be like a whip to drive it along. You may plow under big chunks of cow manure and plant corn expecting a fair crop. The corn does not make its best growth until July and August, at which time the soil is warm and the manure becomes available. The grass must make its rapid growth while the soil is cooler and soluble nitrogen is not being produced. Clark did not use stable manure. He said it brought in too many weed seeds, and unless it was well rotted and fine it was not the stuff to feed a Spring growing crop.

CHEMICAL FERTILIZERS.—Probably no crop is like grass in responding quickly to the right chemicals, and more slowly to the wrong kind. The right kind are quickly available, with a large proportion of nitrogen. One of the best grass growers we know of uses equal parts of nitrate of soda, fine ground bone and muriate of potash. This makes a very strong mixture, and where it is used the grass simply has to grow. Clark used a commercial brand which is much like the following mixture: 400 pounds nitrate of soda, 1,200 pounds fine bone, 400 pounds muriate of potash. There are many different combinations of nitrate of soda, sulphate of ammonia, bone or acid phosphate and potash. The various top-dressers and grass mixtures are made up of these chemicals. The first principle of all is to have the nitrogen in a soluble form so as to force the grass from the start. It would be a mistake to feed this kind of grass on the theory of returning to the soil what the hay crop removes. You must add that much and more in order always to have a surplus of plant food in the soil. There will be little if any loss on a crop like grass, which keeps the soil constantly filled with long roots. Clark used about 800 pounds of his mixture at seeding; mixing the chemicals thoroughly in before the seed was scattered. Thereafter he used 600 or more per acre in the Spring—which is the proper time for fertilizing grass. In some cases when the latter part of the Summer was wet another application was made after haying so as to force a heavy second crop of grass.

A RACK USED WITH A HAY LOADER. FIG. 416.

SEEDING.—Most farmers use grass seed with wheat or rye in the Fall or oats or barley in the Spring. They think the grass does better with a "nurse crop," and they need the grain. Such seeding is usually part of a rotation in which small grain finds a part, and where there is no desire to put down a permanent meadow. Such farmers expect one crop of wheat or rye, one of clover, and one of Timothy—then the soil is plowed for corn. What we are talking about now is a permanent meadow, where the grass will be cut eight or 10 years. We have such a meadow seeded on a modification of this Clark plan nine years ago, and still giving good crops of fair grass. Clark objected to the grain or "nurse" crop for several reasons.

LIME AND CULTIVATION FOR ALFALFA.

THE pictures shown on page 966 are taken from Bulletin 178, Kentucky Experiment Station at Lexington. A thorough study of the needs of the Alfalfa plant for Kentucky soils was made to give the basis for the figures shown in this bulletin. The picture, Fig. 414, shows the difference in the growth and appearance of Alfalfa on soil that was thoroughly limed and soil of much the same character which was not treated with lime. As a general proposition the use of ground limestone gave an increase of 3,220 pounds of Alfalfa in four cuttings. It was also noticed that on unlimed parts of the field the wheat growth was much heavier. The hay from the first cutting where the lime was not used was nearly half weeds. It was found that four tons of ground limestone per acre was the most profitable application for Alfalfa on this soil. The point to be made from this experiment is the fact that Alfalfa is a lime loving plant and cannot be expected to give a good account of itself except upon a natural lime soil or where heavy applications of lime are made. These facts would indicate that Alfalfa may not be the most profitable crop in many sections where soil is deficient in lime and where the lime must be hauled long distances and thus sold at a high price.

The other picture shows a device used for cultivating Alfalfa. This work is done on the farm of W. P. Givens, a well-known Kentucky farmer, who grows 100 acres of Alfalfa. Mr. Givens has been so successful with the Alfalfa that he finds it more profitable than tobacco, and has given up the latter crop. Immediately after each cutting Mr. Givens cultivates the Alfalfa soil with a spring-tooth harrow such as is shown in the picture. The teeth of this harrow are filed down to a sharp point. Thus it scratches and tears up the ground until, as Mr. Givens says, "it looks almost like a cornfield prepared for planting." The Alfalfa is not injured, however, by this treatment, but it comes up afresh and makes a new and better crop to pay for the cultivation.

SHALL WE PLOW THE SOY BEANS UNDER?

WE have two acres drilled to cowpeas, and two to Soy beans, side by side, to be plowed this Fall for raspberries, to be set next Spring. We wish to know whether lime should be added this Fall or next Spring, and how much would be best to use? C. L. A.

Ohio.

Unless there is some special reason for doing so we would not plow this Fall. In the case of the Soy beans we should sow rye and turnips in the Soy beans the same as in corn. Cultivate the seed in and let them alone. They will die down at frost and during the Winter mat on the ground. Some little manurial value may be lost by not plowing under, but not more than the cost of plowing, while the rye and turnips will more than make it up. If the cow peas are in drills, we would do the same with them. If they are broadcast, scatter the rye and turnips right among the vines while the ground is wet after the rain. In the Spring we would plow the dead vines and turnips and the living rye and use half a ton of ground limestone per acre. The raspberries do not respond freely to lime and we would not use slaked lime in preparing for them. We imagine your soil needs potash as well as phosphoric acid. We should use 400 pounds of acid phosphate and 125 pounds sulphate of potash per acre. The best time to use these chemicals is in late Summer—after picking—during late cultivation. At this time the plants are forming their fruit buds for the next crop.

FARMERS' CLUB

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Poisoning Army Worms.

THIS is the "bait" suggested by the Department of Agriculture for killing the army worm:

If the worms are already in the field the following mixture which will attract the worms and destroy them should be spread about. One pound of paris green (poisonous); 50 pounds of wheat bran; juice of one-half dozen oranges. Bring this mixture to a stiff dough by the use of dilute molasses and scatter it amongst the worms. Care should be taken to keep this dough from children or domestic animals.

Preventing Ivy Poisoning.

THE following treatment for poison ivy is, I think original with me. The poisonous principle is a volatile oil, hence aqueous liquids do not remove it, and alcohol only imperfectly. The following treatment is preventive, if taken in time. Take a bit of absorbent cotton, dip in common commercial ether, and brush over the affected place. Rub thoroughly, but with little pressure, repeat the process, using more pressure. I am positive that there will be no symptoms of poisoning. The reason is that ether is the best solvent we have for oils; and it removes the poisonous oil, obviating the trouble before it is beyond the itching stage. After removing the poison with the ether, any of the usual remedies will be much more efficacious. Personally I find a saturated solution of lead acetate (sugar of lead) in 60 per cent. to 70 per cent. alcohol gives the best results.

New York. IRA ULMAN, M. D.

Applying Commercial Fertilizer.

I WISH to try a little commercial fertilizer this season, plowing up a poor Alfalfa stand which was nicely topdressed last Fall, and am thinking after I finish planting I can sow broadcast some bone meal or dried blood, acid phosphate, and sulphate of potash and thoroughly harrow it in and get good results. I have never used any common fertilizer.

Wisconsin. F. R. C.

On our eastern farms, where chemicals are freely used, and where the soil does not contain so much organic matter, the usual advice would be to use one part dried blood, three parts fine ground bone and one part sulphate of potash—all by weight. This would surely give good results on late planted potatoes where a clover sod was turned under. Many farmers would feel that the dried blood was not needed, since the sod supplies a large quantity of organic nitrogen, yet the best farmers would probably use it in order to insure the crop. Where the manured Alfalfa sod has been plowed under there ought to be enough organic nitrogen to feed a heavy crop of late potatoes, and the theory would be to furnish potash and phosporic acid in abundance. This would be done by the bone and potash alone. As an experiment we should like to see the dried blood added for an acre or so to see if extra organic nitrogen would give results.

Bisulphide of Carbon for Squash Borer.

IS bisulphide of carbon an absolutely sure preventive of the squash vine borer? I planted some cucumber seed a month ago, and the vines are now about six inches high and beginning to spread. Would it be too late to apply some bisulphide of carbon? Ho close to the vines should it be put, and how much to each hill? Would it have any injurious effect on the vines?

Cleveland, O. H. N.

Bisulphide of carbon will exterminate any borers present in the soil around the vines, and in most cases those that have not buried themselves too deply in the vine stems, but the bisulphide being of an extremely volatile nature, it is effective for only a short period after application, and is therefore in no wise a preventive against the attack of a later brood of the borers. The bisulphide will not injure the plants in moderate applications; about a teaspoonful applied to each hill at each application will be sufficient. Take a broom handle or similar stick, and make a hole about four inches deep at one side of the hill two or three inches away from the plants, into which pour a measured teaspoonful of the bisulphide and immediately fill the hole with damp earth. In a few minutes the gas will penetrate all through the soil for some distance in every direction, and kill every insect with which it comes in contact. The application may be repeated in about a week or 10 days if it is thought necessary. Bisulphide is highly explosive, and great care must be taken when handling it that fire does not come in contact with it, or a serious accident might occur. K.

Blighted Cucumbers.

MY pickle plants are all dying. They seem to wither up and turn back from the root. What is it?

Englishtown, N. J. MRS. C. H. R.

Blight, mildew and stem borers are the three worst destructive agents the grower of cucumbers has to contend with, either one of which might be responsible for the condition of these plants, owing to the great amount of rain and cloudy weather which has prevailed all along the Jersey coast section for the past three weeks. I am strongly of the opinion these vines have an attack of mildew, but whatever the cause may be, whether mildew, blight or stem-borer, the trouble will be of considerable difficulty to combat successfully. Plants that have been attacked with mildew or blight are usually beyond recovery in a few hours after it is first noticeable, and are beyond the reach of remedial agents. All infected plants should be pulled up and destroyed, and as a preventive from further spread of the disease the remaining plants should be thoroughly sprayed every 10 days with Bordeaux, 3-6-50 formula, which can be purchased from dealers in insecticides and fungicides.

The stem-borer is not nearly as destructive as the mildew or blight, and may be combatted with success by soaking the ground around the stems of the plants thoroughly with a strong tea made from tobacco stems. This should be applied every week or ten days. Bisulphide of carbon may also be employed for the purpose, with a broomstick. Make a hole near the plants about four inches deep, into which pour a small teaspoonful of the bisulphide, and immediately cover up with damp soil. This quantity will be sufficient for each hill, and may be applied once in 10 days without injury to the plants. Bisulphide of carbon is highly inflammable, and must not be brought in close proximity to fire, or a serious accident may occur. K.

Stocking Pond With Bass.

I HAVE a small lake that I would like to stock with bass. Can I get any bass from the State hatcheries? If so what course would I have to take to get them? F. W. W.

Chappaqua, N. Y.

If there are trout in your lake it will be a violation of State law to put bass there. If not, you can get bass from the New York State hatcheries on application to the Conservation Commission, or your Congressman might get them for you from the U. S. Bureau of Fisheries, but that would make the lake public water so far as fishing is concerned, and you could not prevent anyone from taking the fish so long as they did not land on the shore of the lake or its outlet. If the lake or its outlet or inlet has been stocked with fish by the State since April 17, 1896, it is public water. You should write to the Conservation Commission for a copy of the Game Laws, and read the part beginning with Section 360, in regard to private parks.

I cannot tell from your letter which kind of bass would do well in your lake. The large-mouth is the better pond fish, but the small-mouth sometimes does well in spring ponds with stony or gravelly bottom. A lake well adapted to small-mouth bass would be likely to be fitted for trout, and I should advise planting them. A. C. W.

GARDEN FARMING, by L. C. Corbett. This book is a manual of vegetable culture giving especial attention to truck farming, as carried on in the various sections of the United States. In addition to cultural methods, marketing, packages, etc., are discussed. Prof. Corbett is well known as an authority upon these subjects and this book will add much to the farmers' knowledge. Published by Ginn & Co., New York; 463 pages, many illustrations, price $2.00.

Good-bye, Mr. Fertilizer Agent

I'm going to mix my own fertilizer, and save $10 per ton. Got better crops, at less cost, last year with

Home Mixing

Why pay $4 to $12 per ton for ready-mixed fertilizer? You can do it yourself just as well, and put money in your pocket. Departments of Agriculture and Experiment Stations all say: "Mix Your Own Fertilizer." No filler to pay for or haul. Better materials. Lower cost.

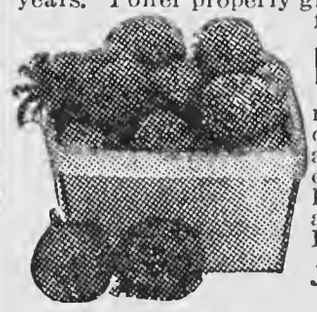
STRAWBERRY PLANTS
POT-GROWN AND RUNNER
For AUGUST and FALL planting. Also Raspberry and Blackberry Plants. All Leading Varieties. Catalogue Free. HARRY L. SQUIRES, Remsenburg, New York

Plant LOVETT'S Pot-Grown Strawberries
this Summer and have an abundance of big, red, luscious berries next June
I am a pioneer in growing Pot-Grown Strawberries. I have been growing them for 36 years. I offer properly grown plants of all the choice new and good old varieties—but by far the finest of all strawberries are the Van Fleet Hybrids, the



Early Jersey Giant, Edmund Wilson & Late Jersey Giant
now being introduced by me. They yield enormously, have the delicious flavor of the wild strawberry, and are as large as small apples. These three varieties give a long season of fruit, from the earliest until the very latest. Write for my booklet, mailed free. It tells all about the Van Fleet Hybrids, illustrates and describes a score or more of other fine varieties (including the best of the Everbearing Strawberries), and gives *full cultural instructions.*

Farm Engineering.

Foul Water.

COULD you advise what can be done as to the following? We have a dug well about 30-32 feet deep, in which we have a pump. Each year about this time the water seems to become contaminated; at any rate it develops a very bad, foul taste. Could you suggest what can be done to remedy that? What can be done to purify, etc? J. S.
New York.

It is possible that the fertilizing of the fields at the Spring time of year is responsible for the contamination of your well, particularly if the well is not walled up and plastered so as to positively prevent any water getting into the well without sinking through 20 feet of soil. Even then, if the fields or your barnyard are above the well or near to the well, the water may become contaminated. I would suggest that you send a sample to the Agricultural College at Ithaca for analysis. R. P. C.

A Cistern Filter.

I WISH to secure information in regard to the construction of a cheap cistern filter. Can you give me any assistance? G. M. T.
Monroe, Me.

The cheapest and best cistern filters are sand filters, described frequently in THE R. N.-Y. The whole object is to cause the water to sink through clean, fine sand. Usually, the bottom layer in the box or barrel used for a container, is six inches of coarse gravel, then a layer of lump charcoal about two or three inches thick, then a four-inch layer of fine gravel, a similar layer of coarse sand, a second layer of finer sand and a top layer of still finer sand. The sand and gravel must be washed free from loam and dirt. Each layer is laid individually and packed before another layer is put on. No extremely fine sand should be used, and the filter should not be disturbed more than perhaps twice a year, when the top layer should be carefully scraped off and replaced by a layer of clean sand. The water should be caused to flow into the filter without great force so that the sand will not be disturbed. R. P. C.

Fixed Oils in Concrete.

WHAT about mixing "fixed oils" with concrete? Will it make waterproof walls and floors warmer or colder? Will such mixed cement on wire lath make a waterproof wall? Will it alter the rot-producing tendency on wood in contact with such? Ordinary concrete is said to rot wood. S. H. S.
Deposit, N. Y.

We have been unable to determine what is meant by your term "fixed" oils. Many soap or oil emulsions are added to cement to form a jelly in the pores, plugging them up. Surface coatings of paraffin diluted in gasoline or xylol are frequently used. The effect on floors as regards heat or cold is not appreciable. Of course, a damp floor would appear to be colder because of its greater heat-conducting power. Wood imbedded in concrete does not, but it is usually dry rot. I should expect any waterproofing might increase this tendency slightly. R. P. C.

Raising Water With Ram.

I WISH to use a ram in a spring for half-inch pipe, 500 feet from house to spring, a three-foot fall. I would like to raise the water 15 feet upstairs for a bath room. W. H. R.
Tyler, Pa.

You can use a ram with a fall of three feet and readily raise the water to a height of 15 feet with even a small ram. A No. 4 standard ram will require three or four gallons a minute from the spring, and will deliver to a storage tank placed, say, 20 feet high, about 20 gallons per hour. The pipe from spring to ram should be 25 feet long (at least) and 1¼-inch diameter. The pipe from ram to tank can be ½-inch. The ram will cost about $7.50. The pipe (galvanized) will cost about 10 cents per foot for the large and five cents per foot for the small size.

The ram will work constantly day and night as long as there is a flow of water, so a storage tank will be needed. The water can flow from the storage tank to the house faucets by gravity. Place the ram in a pit a few feet deep and 25 or 30 feet from the spring. Lay a tile drain from the pit to take off the waste water thrown out by the ram. R. P. C.

Porch of Cement and Cobblestones.

WE intend to build a new porch 22 feet long, turning at corner and running 16 feet to side entrance; porch as planned to be eight feet wide and at least seven eight-foot columns 10 inches in diameter, which cost us about $3 each. Cobblestones are very plentiful with us. We wondered if we could not build a wall across front of porch using stones and cement, then build up from top of wall the columns of cobble and cement. Which would be cheaper? How much cement is required? Would eight feet wide be all right, or would you make it 10 feet? Would you use cement floor or matched flooring? We do most of the work ourselves. S.
Chenango Co., N. Y.

The wood floor will suit you better, and the cost will not greatly exceed the cement, if it exceeds it at all. The cobblestone-cement column would be very attractive and undoubtedly cheaper—how much cheaper it is not possible for us to figure. Eight feet is a good width. The extra two feet are not worth the extra cost. R. P. C.

CROPS

In a recent electrical storm (July 10-11), a large number of acres of corn, potatoes and buckwheat were badly cut up with the hail. In the bottom lands the large creeks were overflowing their banks, covering with gravel and sand crops of all kinds. This will make a shortage in this section. Otherwise everything will be about 30 per cent. better than last year. A. W. L.
Richmondville, N. Y.

The ground is very dry; rain is very much needed. Farmers have finished sowing buckwheat, and are now busy haying. Corn, potatoes and oats are looking well. The bulk of the hay crop is light; the average run of old meadows will cut only a little over half as much as in years past. New seeded meadows are fair. Farms are in good demand in the vicinity of Chautauqua Lake, a great many have been disposed of the past year.
Mayville, N. Y. P. S. S.

I note in your issue of July 11 that the peach crop is "spotted." The little spot around this town is full of peaches, the trees already bending nearly to the ground, and as there have already been sold 400,000 half-bushel peach baskets, prospects are that there will be nearly 700 cars shipped from this station. Room on the trees being limited, many double peaches have been formed. We need help to pick and pack this fruit, and most of all to reach as many consumers as possible. A. L. T.
Smithburg, Md.

June 29.—Pastures are better than in several years at this season, and showers are frequent so will probably continue good. Milk, which is the main money product in this section, is 10 cents per can of 85 pounds below the price of a year ago. The Holstein is kept almost exclusively, many purebred; 90 per cent. of the farmers using purebred sires. One sale has just been made by a neighbor of five cows and six yearling purebreds, for $28. Many cows, both pure and grade, are bought here and shipped West. There is great interest in Holsteins here, one boy of 19 years having a four-year-old grade giving 97 pounds a day, last January. The soil is limestone and much Alfalfa is grown, the first cutting being well taken care of now, a heavy yield, but not quite so good as last year, some raising nothing else. Oats and corn are looking fine. Prospects for apples are poor, worms of different kinds injuring the trees; small fruit plentiful. J. C.
Mannsville, N. Y.

July 13.—We are having a dry Summer here in Hillsdale Co., Mich. Our early potatoes are very small and few in a hill. I planted one acre, and a larger or a finer growth of vines I never saw, but no potatoes. They were on heavy gravel land, used for a hog lot for ten years, and very rich. They are Early Rose, very free from weeds or bugs. The ground is fine and loose and seems to be moist enough. Our oat crop is short straw, and thin on the ground. Hay is about one-half crop. Small fruits plentiful; apples, peaches and pears scarce. The scale has killed most of our apple trees. People here have commenced spraying their orchards, and this seems to check the scale. Stock of all kinds here is high and scarce. The automobile craze has taken a large amount of money out of the country, so it bothers the farmers to get enough to do general business. Labor is high and hard to get on the farm at any price, especially in the house. Our young men are going to the cities and leaving the farm. What the result will be is hard to tell, but I believe that the boy who stays on the farm will win out. The best proof of this is our bank deposits, which are largely made by the farmers. The only remedy I know of is to use more brain and muscle and be a producer instead of a kicker. J. A. P.
Camden, Mich.

There will be practically no fruit through the Schoharie Valley, due to the cold weather that prevailed through the latter part of April and the first part of May. Hay is the lightest crop that can be recollected, due to the drought through April and May. Rain came May 20, which was too late for hay, as it was nearly matured. Farmers have had a very poor catch of seeding for the past seven dry years. Corn came up very uneven, but the late rains have benefited it as well as oats, buckwheat and garden truck. A very small acreage of rye has been sown the last few years on account of the dry seasons that prohibited plowing. Much of our soil is clay or a sand loam with a heavy clay subsoil. Many farmers have turned their attention to dairying; most of the milk is sold to Bordens. They received $1.10 for June for a 3.8 test, with a premium of 10 cents for good stable and milk conditions. The creameries formerly were mostly co-operative, but Bordens have succeeded in buying nearly all of them. The farmers at Schoharie have become dissatisfied with selling to Bordens because they formerly got their skim-milk back, and have to have better stables and milk conditions. They called a meeting July 8 for the purpose of erecting a co-operative creamery. There was a small attendance because many of the farmers are busy in harvest; nevertheless a meeting will be called soon. It is reported nearly all are in favor of a co-operative creamery. Cows are selling from $50 to $75; calves, nine cents, live; eggs, 20 cents; butter at local stores, 25 cents. There is a shortage of farm laborers this Summer; wages range from $20 to $30 with board. Schoharie County has been a great hop country for years, but the percentage of yards now is small, due to the blue mold that gets all that are not sprayed several times with brimstone. Prices prevailed around 38 cents last Fall and Winter. Farm machinery sales have been small this season, due to the early drought, which discouraged the farmers. The bee-keepers report a light crop of honey, due to very little clover and basswood, but the prospect for buckwheat looks good to them. Farm sales are scarce, prices from $20 to $90 per acre. Schoharie County is the only county in the State that has no city. The tax rate is high on account of the numerous bridges on the Schoharie River. A. B.

West Kansas on the Boom.

The abundant rainfall which extended over the western third of Kansas from April 1 to July 15, has brought about the biggest crops known in the history of the State. The soil throughout this section of the country is remarkable for its natural richness (no fertilizers ever being used), and its capacity for retaining all the moisture received for long periods of time. Rainfall since April 1 has averaged 2½ inches per week. The potato crop is immense and a large per cent. of the farm folks are enjoying vegetables from thrifty home gardens. There is a large acreage of feed—cane, milo, millet and kaffir. Late rains have assured a large yield of these. Wheat harvest is on, the average fields making 30 bushels per acre. But little rye was sown. Oats made 40 bushels. Thousands of acres of corn are in tassel and with one more rain in early August will go 50 bushels to the acre. P. C.
Jennings, Kansas.

Everjet
Elastic Paint

Everjet is a lustrous black carbon paint that combines low cost with durability. It will not rub, peel or scale. Never becomes brittle; cannot crack. Absolutely waterproof and acid proof. Best for all exposed metal and woodwork.

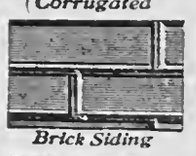
Lowest Prices Ever Made On World's Best Roofing

Edwards Patent "Grip Lock"

Corrugated



Brick Siding

Ceiling

Lightning-proof, Fire-proof, Rust-proof, Rot-proof, Galvanized Steel Roofing Lasts as Long as Building Stands

Once you have purchased and laid Edwards Tightcote Galvanized Steel Roofing your roofing expense for that building is at an end.
Its cost per square is the lowest ever made. It has *no* up-keep cost. Always beautiful in appearance. Reducing cost of insurance.

EDWARDS Exclusive Tightcote Process

Makes Rust-Proof Roofing. The zinc spelter becomes practically one piece with the steel. No ordinary galvanizing can compare with it. Each and every Edwards Metal Shingle, Metal Spanish Tile, each sheet of Edwards Reo Steel Shingles, Grip Lock Roofing, Pressed Standing Seam or Roll Roofing, Ceiling, Siding, etc., is dipped in a bath of molten zinc, one at a time, after the metal has been stamped and resquared. The edges are galvanized as heavily as the sides. Not the space of a pin-point on steel exposed to weather.

How To Test Galvanizing

Take a piece of any other galvanized steel, bend it back and forth several times, hammering it down each time. You will then be able to flake off great scales of the galvanizing with your finger nail. Apply this test to a piece of Edwards Tightcote Galvanized Steel Roofing—you'll find no flaking.

EDWARDS Patent Interlocking Device

Prevents Warping, Buckling or Breaking, Protects Nail Holes—they can't Leak or Rust. Nails are driven through the under layer not exposed to weather—cannot rust. No special tools or experience needed to lay this Roofing; anyone can do the work—lay over old shingles if you wish.

Reo Steel Shingles

Cost Less, Outwears 3 Ordinary Roofs and are your joy and pride forever. No matter what kind of a building you have in mind there is a style of EDWARDS Galvanized Roofing exactly suited to your needs.

FREIGHT PAID Lowest Factory Prices

Greatest roofing proposition ever made. We sell you direct—*save you in-between dealers' profits.* No matter what your building is, we simply ask the right to prove to you that our prices are lowest ever made for World's Best Roofing. Postal or coupon brings Roofing Book No. 873.

Acetylene Ranges For Quick Cooking In Country Kitchens

You housewives in the country who labor over hot stoves cooking big meals for hungry families—how would you like this convenience, which every city woman enjoys?

How would you like to do your cooking on a gas range?

How would you like to turn on your gas with a twist of your wrist—turn it up or down just as hot as you want it.

If you have ever been in a city kitchen you know how much such a range will shorten your cooking hours and relieve you of the trouble and work of handling kindling, coal and ashes.

You also know what pleasure and comfort your household will derive from brilliant Acetylene lights throughout your house and barns. To date this convenience—Acetylene for Lighting—Acetylene for Cooking—has been supplied to over 250,000 country homes.

Pilot Acetylene generators are today the most widely sold light and fuel plants in the world.

The Pilot is extremely simple to operate. You simply fill the generator with water and Union Carbide about once a month. The machine then works automatically without further attention.

It feeds the gas it makes—genuine Acetylene—direct to your kitchen range, and to stationary light fixtures, yielding handsome, brilliant, white light throughout your house and all the barns and outbuildings as well.

For full information, estimates, etc., address

Oxweld Acetylene Company

654 Frelinghuysen Ave., Newark, N. J.

EVENTS OF THE WEEK.

DOMESTIC.—Charles Purcell, who admits a long criminal record, was held in $10,000 bail July 16 for the grand jury by United States Commissioner Houghton, at New York, charged with using the mails to defraud. Purcell, alias Mason, was arrested at the Pennsylvania station by Post Office Inspectors O'Brien and Entemann, of Philadelphia, immediately after he had shaken hands with Albert W. Weblin and wife, who alighted from a train from Villanova, Penn. The Weblins, according to Inspectors O'Brien and Entemann, came over from England a few months ago to care for the estate of William Hepburn, of Villanova. They wanted another place, and soon after they had advertised in periodicals, they said, they got a letter from Purcell, signed "Charles Mason," asking them to care for the large estate of his sister in Westchester County, N. Y. They said he offered $80 a month and board, but as they would have to look out for considerable money he asked them to send him a $300 bond. The Weblins suspected something and got Purcell to send on his photograph. They took this to Philadelphia, and Inspectors O'Brien and Entemann arranged to trap Purcell. He was committed to the Tombs.

The fire on the Bronx side of the Harlem River, New York, July 16, destroyed the big plant of the New York Yacht, Engine and Launch Company, the coal pockets of the Olin J. Stephens Company, extending from 175th street to 177th street, and four yachts on the ways in the shipyard. The damage is placed at $200,000. Fifty horses in stables adjoining the burning buildings and boats moored in the shipyard were saved by the quick work of policemen.

After a pitched battle between several hundred striking coal miners and sympathizers and 100 guards stationed at the Prairie Creek mines of the Mammoth Vein Coal Company, near Fort Smith, Ark., July 17, which ended in the rout of the guards, tipples of three mines were destroyed by fire and dynamite. The property damage is estimated at $200,000.

Whipple, Sears & Ogden, representing minority stockholders, brought suit in the Supreme Court at Boston, July 17, for the appointment of a receiver to prosecute claims aggregating $206,000,000 against directors and estates of directors of the New York, New Haven and Hartford Railroad. It is set forth in the bill of complaint that these defendants, by authorizing the acquisition of the Boston and Maine Railroad and various trolley and steamship lines, wrongfully withdrew $162,000,000 from the New Haven company "ultra vires and for illegal purposes" and are therefore responsible for the return of this amonnt. It is further alleged that the losses resnlting from these aeqnisitions approximate $102,000,000, and that the railroad company is accordingly entitled to recover triple damages, or $306,000,000, under the terms of the Sherman anti-trust law.

After litigation that began 12 years ago in the New York Supreme Court and went to the United States Supreme Conrt, R. H. Macy & Co. entered judgment in the Snpreme Court July 17 for $140,000 against the American Publishers' Association and the American Booksellers' Association. The judgment was paid at once by certified check. The suit was the outgrowth of the defendants' rule which fixed the retail price of their productions. R. H. Macy & Co. resented the effort of the book pnblishers to compel them to adhere to this fixed price system.

The seventh case of bnbonic plague was annonnced at New Orleans July 17.

The premature explosion of a 4,800-ponnd dynamite charge at Cucaracha slide, Canal Zone, July 20, killed five workmen, four of them white, and severely injured one white man and seventeen negroes. The workmen were aboard the drill barge Teredo, which was wrecked and sank in the channel. The men had just completed charging the last of eight drill holes with 600 pounds of 60 per cent. dynamite, when the explosion occurred. The charge was to have removed the last stone in the channel cut.

Serious trouble occnrred at Vancouver, B. C., July 19-20, in the attempt to prevent Hindu immigrants from landing from the Japanese steamer Komogata Maru. The Vancouver authorities are determined to prevent the landing of any Asiatics.

FARM AND GARDEN.—Eight railroads were fined an aggregate of $30,000 by Judge Landis at Chicago, Jnly 17, for violation of the law providing that livestock in transit must be fed and watered at least once every 28 hours. The roads penalized were the Chicago, Rock Island & Pacific, the Chicago & Northwestern, the Chicago, Bnrlington & Quincy, the Illinois Central, the Baltimore & Ohio, the Chicago & Great Western, the Grand Trunk and the Chicago & Alton.

Third annual meeting of the Cumberland White-Egg Runner Club will be held September 1, at the Poultry Building, State Fair, Syracuse, N. Y. The first session will be held at 11 A. M. and another in the afternoon. Any new members will be welcomed and may then join. Initiation and first year's dues, $2. C. S. Valentine, Ridgewood, N. J., president.

Army worm invasion is reported from many different localities, including Philadelphia and Baltimore, as well as New York State. The grasshopper plagne is also severe in upper New York State.

An informal field meeting of the Northern Nut Growers' Assoeiation will be held on Tnesday, August 4, or on Friday, August 7, if Tuesday should be very inclement, at Merribrook Farm, the home of Dr. Robert T. Morris, Stamford, Connecticut. Methods of budding nut trees and Dr. Morris's new inareh method of grafting will be demonstrated, and the results of his past work in propagating and hybridizing nut trees may be seen.

The Delaware Valley Co-operation Assoeiation, which the farmers and milk producers of Belvidere, N. J., and vicinity have formed, is a very strong organization having at this time some 82 members. They have planned the ereetion of a modern sanitary ereamery in Belvidere, N. J. They are now waiting on some legal matters pertaining to their charter, when they will have the erection of their building pushed rapidly. The officers of the association are: A. Russell Paul, president; Levi C. Mackey, treasurer; Sam Fitts, secretary; Jay J. Hartung, W. A. Mackey, Henry Stahl, Geo. Hummer, viee-presidents; Albert Smith, Sheldon Bush, W. C. Hartung, Wm. Hess, Geo. R. Good and Erwin Butz are the directors. All of the officers have been very active in a reeent demand made for a better priee for their milk, whieh being refused by the Castanea Dairy Co., has awakened a feeling of greater activity among the producers. At the time they made their demand for a better price for their milk the creamery was paying them 2½c. per quart.

BUFFALO MARKETS.

ALL berries are plentiful, but raspberries are sometimes to be had as low as seven cents a quart, though that is their lowest regular wholesale quotation. Reds and creams are 10 to 13 cents. Cherries are also low, but they are so lean that the value is mostly small, quoted at five to nine eents a quart, with enrrants same, blackberries 10 cents and blueberries, not plenty, same. Plums, red and blue, retail at about a cent apieee. Currants are very plenty at 25 cents a basket or six cents a quart, gooseberries same. Currants are also rather small and not as attractive as they might be. Peaches are beginning to appear in quantity, though the big baskets are not here yet. They are qnoted at $1.50 to $2.50 per crate, coming chiefly from California. The quality is good for early specimens. There is no promise of nearby offerings. New apples have now about crowded old ones out, new Southern selling at 75 cents to $1.50 per hamper, reds selling for half more than greens. There is a good snpply of melons, bnt prices remain np, largest watermelons running as high as 40 cents and muskmelons $2 to $2.75 a crate. There is a variety of small muskmelons retailing at five cents each, of very good quality. Wax and green string beans are down to 50 to 65 cents a bushel, and lettuce, 20 cents a dozen. Some mammoth heads retail at five cents a head. Cucumbers are 15 to 50 cents a dozen, retailing at three for five cents, medium sizes. Cabbage continues at four to five cents a head at wholesale and homegrown onions are $1.20 a bushel; homegrown tomatoes, $2.25 a bushel; peppers, $1.50 per box. There is still a little celery at 20 to 35 cents a dozen. Beets are down to 10 to 15 cents a dozen bunches. Butter is not quoted above 50 cents, which is a cent up from a week ago. The retail price is somehow only a cent or two more. Cheese is a little lower, the range being 12 to 16 cents, wholesale. The egg supply is large and fancy wholesale at 27 eents. The lowest quotation is five cents lower. Poultry is firm at 21 to 22 cents for dressed turkey, and 15 to 17 cents live; fancy fowl, 18 to 19 cents dressed, 16 to 17 cents live; large broilers, live, 23 to 24 cents. J. W. C.

COMING FARMERS' MEETINGS.

Georgia State Horticultural Society, Snmmer meeting, Griffin, Ga., Augnst 5-6.

International Apple Shippers' Association, twentieth annual convention and apple exhibit, Copley-Plaza Hotel, Boston, Mass., August 5, 6, 7.

Thirty-ninth Annual Convention of the American Poultry Association, to be held at Chicago, Ill., August 8th to 15th, 1914, inclusive.

Northern Nut Growers' Association, annual convention, Evansville, Ind., August 20-21.

National Dairy Show, Chicago, Ill., October 22-31. The following meetings and conventions will be held in connection with the show: American Association Creamery Butter Manufacturers, Oct. 26. Holstein-Friesian Assoeiation of America, Oct. 26. International Milk Dealers' Association, Oct. 26 and 27. Conference, Secretaries of State Dairymen's Association, Oct. 27. Official Dairy Instructors' Association, Oct. 27. National Dairy Union, Oct. 28. American Dairy Farmers' Association, Oct. 28. Council of the National Dairy Show, Oct. 28. National Association of Creamery Managers and Owners, Oct. 28. Amerieau Jersey Cattle Club, Oct. 28. National Association of Iee Cream Mannfacturers, Oct. 28, 29 and 30. International Assoeiation of Dairy and Milk Inspectors, Oct. 29. American Guernsey Cattle Club, Oct. 29. Congress of Marketing, Oct. 29. Milk Producers' Association, Oct. 30.

Annual Show of the Paterson, N. J., Poultry, Pigeon and Pet Stock Association, November 18-21.

Indiana Apple Show, Tomlinson Hall, Indianapolis, Ind., November 18-24.

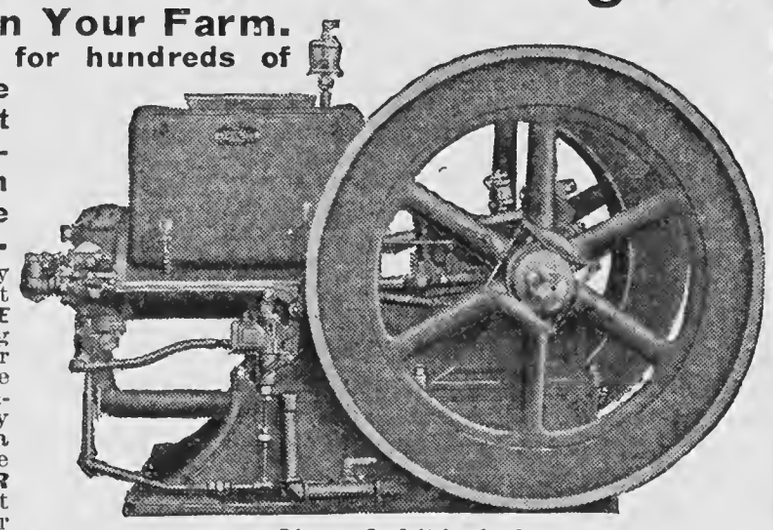
It's making money for hundreds of farmers. It will make money for you. Get our special proposition to one farmer in each locality. We save you money.



MR. FARMER, YOU simply cannot afford to be without an ***EXCELSIOR GASOLINE ENGINE.*** They are willing workers, never ask for shorter hours or more money. They are the one engine that's always "Johnny on the Spot." There are a lot of gasoline engines on the market, but the ***EXCELSIOR LEADS THEM ALL.*** Let us prove this right on your own farm. Set the ***EXCELSIOR DOING WORK.*** If you find it is the best engine you ever saw or used, keep it; if you don't like it, send it back. You don't have to send any money in advance; you don't have to sign any notes; just take the engine and use it; buy it if you find it is what we say—the best engine made. ***BUT DON'T DELAY—WRITE NOW, TODAY.***

R. CONSOLIDATED GASOLINE ENGINE CO., 202 Fulton St., NEW YORK CITY

Don't Trust Your Alfalfa to Luck

Make sure of a good, big, healthy stand by inoculating the seed with

Ferguson's NITROGEN BACTERIA

Government tests in 34 counties of one State showed that four out of five of the crops without inoculation failed, while almost all the inoculated fields grew fine Alfalfa. Ferguson's Bacteria gather Nitrogen from the air, store it on the roots and feed it to the plants. One bottle contains all varieties of Bacteria for Alfalfa, Clover, Vetch, Peas, Beans—all legumes. Easy to use and costs very little. Soil is left enriched for future crops.

Costs only a fraction as much as the best commercial fertilizer

Quarter-acre quantity, 50c. 1 acre, $2; 5 acres, $9. Let us explain why you need Nitrogen Bacteria and why Ferguson's is best. Write for special booklet N—free.

HOMEWOOD NITROGEN CO.
51 Liberty St., New York City

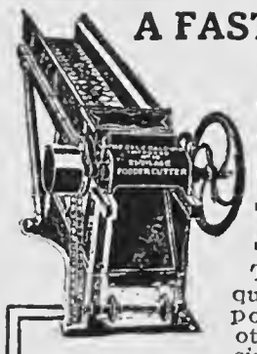
We want agents—a very liberal offer

ALFALFA

CRIMSON CLOVER AND WINTER VETCH. Write today for instructions to obtain larger yields by the use of **FARMOGERM.** Our free illustrated booklet No. R. N. 10 contains valuable cropping receipts and is yours for the asking.

Earp-Thomas Farmogerm Co.
BLOOMFIELD, N. J.

A FAST CUTTER



For Light Power

This Gale-Baldwin requires about half the power demanded by other cutters of similar size. It has a revolving self-feed table—is a strong, positive feeder, and cuts more ensilage per hour than any machine operated with same amount of power.

The Chicopee Line Gale-Baldwin **ENSILAGE-CUTTER**

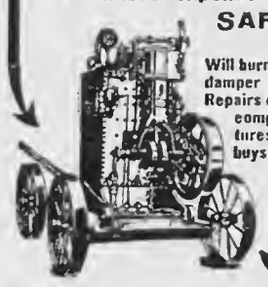
has the widely known, 60-year, B. & T. reputation behind it. That's guarantee enough. Buy one this season, Mr. Dairyman and "thank your star" when silo-filling time comes.

Dealers sell it. If none near you write us. Catalog describing all our line—free. Write today.

Belcher & Taylor Agricultural Tool Co.
Box No. 75, Chicopee Falls, Mass.

Burns Wood or Coal

For steam or hot water for any purpose or at any time without expense of crude oil or gasoline.



SAFE STEAM ENGINE AND BOILER

Will burn cobs or stalks. Governor, water and damper regulators automatic. High speed. Repairs easily made by owner. Furnished with complete equipment of fittings and fixtures. With or without engine. Quickly buys itself. 3 to 15 H. P. May we send you our free complete catalog of rigs?

ONTARIO IRON WORKS
20-40 Olmstead St,
PULASKI, N. Y.

DAISY FLY KILLER placed anywhere, attracts and kills all flies. Neat, clean, ornamental, convenient, cheap. Lasts all season. Made of metal, can't spill or tip over; will not soil or injure anything. Guaranteed effective. Sold by dealers, or 6 sent by express prepaid for $1.

HAROLD SOMERS, 150 DeKalb Ave., Brooklyn, N. Y.

TYPEWRITERS ALL MAKES
Prices $15.00 up. SOLD or RENTED anywhere at ¼ to ½ MANUFACTURERS' PRICES, allowing RENTAL TO APPLY ON PRICE. Free Trial. Installment payments if desired. Write for catalog 15
TYPEWRITER EMPORIUM, 34-36 W. Lake St., Chicago

The Typewriter for the Rural Business Man

Ball Bearing Long Wearing

Whether you are a small town merchant or a farmer, you need a typewriter.

If you are writing your letters and bills by hand, you are not getting full efficiency.

It doesn't require an expert operator to run the L. C. Smith & Bros. typewriter. It is simple, compact, complete, durable.

Send in the attached coupon and we will give especial attention to your typewriter needs.

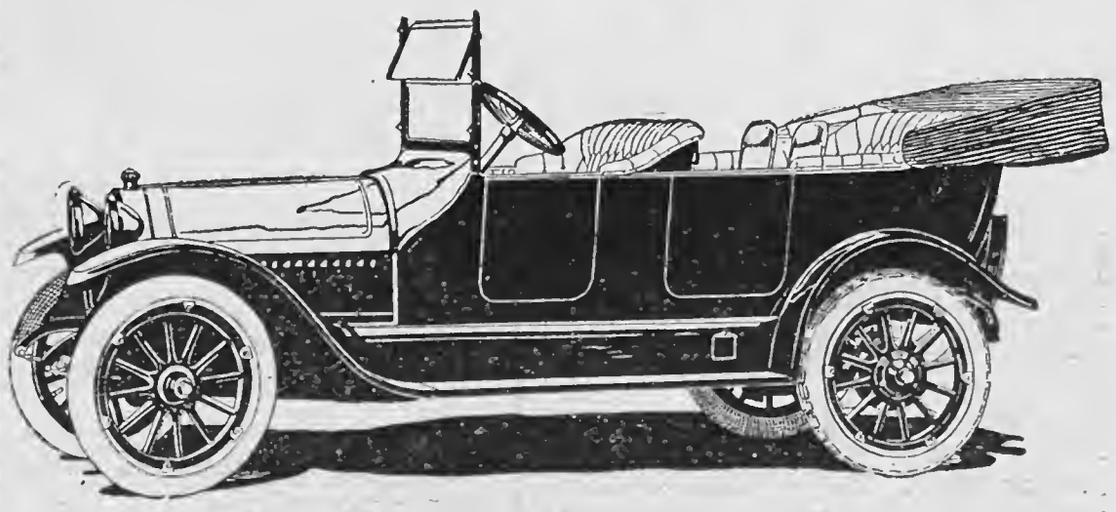
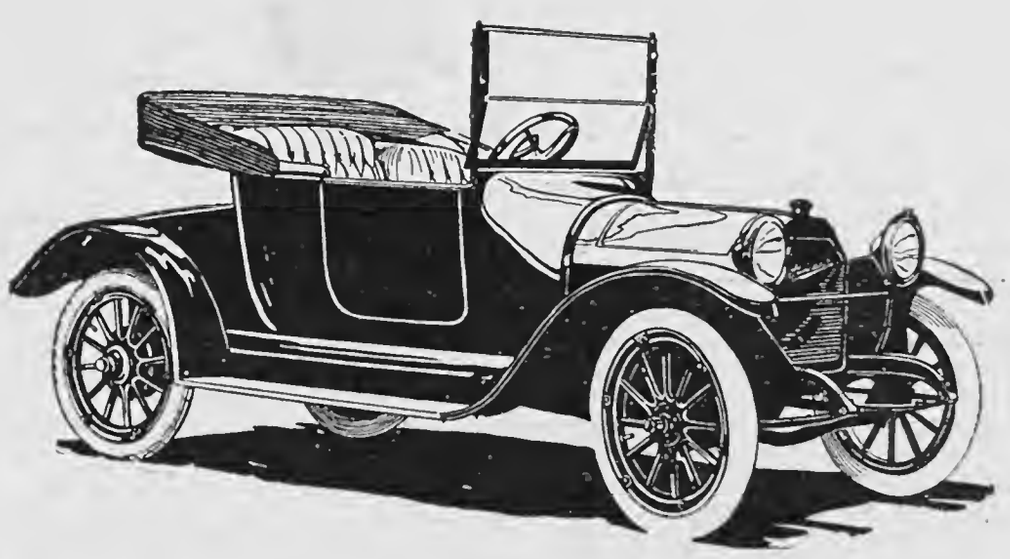
The New Studebaker Automobiles



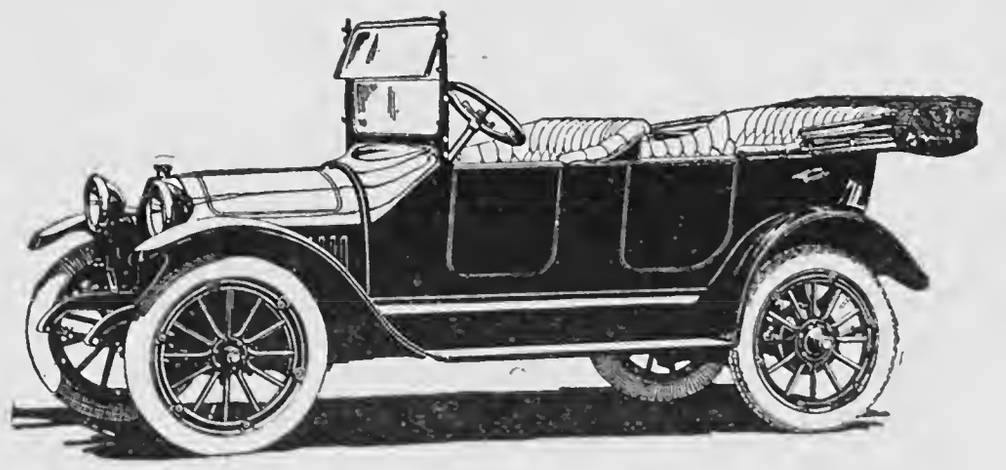
The New SIX—5-Passenger $1385
(7-Passenger $1450)

Two body styles: Five-Passenger and Seven-Passenger Touring.
Wheelbase—121 inches.
Long-Stroke (5-inch), Small-Bore (3½-inch) Motor; Six Cylinders, en Bloc.
Smokeless, Non-Leaking Lubrication System.
Larger Valve Openings.
New, Exhaust-Silencing Muffler.
Annular Piston Rings.
Cellular Radiator.
Lighter Reciprocating Parts.
Crowned Fenders.
Lightened Clutch Operation.
150 Pounds Lighter.
15 x 2½ in. brakes.
34x4-in. Goodrich Tires on Q. D. Demountable Rims; Safety Tread on Rear.
Roomier Front and Rear Compartments.
Continuous Aluminum Footboard.
One-Man Type Top.
Built-in Rain and Clear Vision Ventilating Windshield, Attaching Rigidly to Top.
Scientific Anti-Rumble Gasoline Tank in Cowl.
Magnetic, Non-Leaking Gasoline Gauge, the only One Approved by Insurance Underwriters.
Full-Floating Rear Axle, Shaft Locking into Taper at Hub.
Full Equipment of 13 Timken Roller Bearings.
Irreversible Steering.
Inter-Locking Ignition and Lighting Switches.
24 Finishing Operations in Painting Bodies Studebaker Blue.



The New FOUR Roadster $985

A three-seated roadster that actually seats three grown persons in perfect comfort. Driver's seat set slightly forward. A special top, baggage compartment at rear, etc. Same general specifications as FOUR Touring Car.



The New FOUR Touring Car $985

Two Body Styles: Five-Passenger Touring Three-Passenger Roadster.
Wheelbase—108 inches.
Long-Stroke (5-inch), Small-Bore (3½-inch) Motor; Four Cylinders, en Bloc, Exhaust, Manifold Cast Separate.
Smokeless, Non-Leaking Lubrication System.
Larger Valve Openings.
Pressed Steel Push-Rods.
Annular Piston Rings.
Tubular Radiator with Auxiliary Water Tank.
Crowned Fenders.
Special, Dimming Headlights.
100 Pounds Lighter.
12 x 2½ in. Brakes.
Hot-Jacketed Schebler Carburetor Bolted to Cylinders.
Magnetic, Non-Leaking Gasoline Gauge, the Only One Approved by Insurance Underwriters.
Generous Footroom in Both Compartments.
33 x 4 In. Goodrich Tires on Q. D. Demountable Rims; Safety Tread on Rear.
One-Man Type Top.
Built-in Rain and Clear Vision Ventilating Windshield, Attaching Rigidly to Top.
Full Floating Rear Axle, Shaft Locking into Taper at Hub.
Full Equipment of 13 Timken Roller Bearings.
Irreversible Steering.
Flush Dash Equipment.
Extra Rim and Carrier.
24 Finishing Operations in Painting Bodies Studebaker Blue.

Manufactured Cars on Which You Pay Only One Profit

The Studebaker dealer in your nearest town now has on hand samples of the new Studebaker cars—FOUR and SIX.

Go to him. See the cars.

Inspect them point by point, and your knowledge of automobile construction will impress upon you the splendid safety, strength, stability and comfort of these cars, their fine finish, their generous room, and their complete and liberal equipment.

Through scientific, up-to-date designing and motor refinements, these cars have power in excess of all requirements.

Remember, while you are making your inspection or taking your demonstration ride, that these cars are manufactured entirely—except tires, electrical equipment and a few minor items—by Studebaker, in Studebaker plants, and that no plant in the world is better equipped.

Remember also that their prices represent only one profit—the profit of the legitimate manufacturer who has eliminated the parts middleman from his business.

A motor car, to the farmer, is an economic necessity; not a luxury, as to the city man.

It saves his money; it saves his time; it helps him to get higher efficiency out of himself, his men and his land.

And it wipes out of his family forever the isolation and loneliness that are the dread of many farmers' wives, and that drive the boys and girls into the cities and towns early in life.

Just as the motor car is a good investment, so the Studebaker stands first in value among motor cars and we will tell you why.

For 65 years Studebaker has studied the farmers' needs, as a specialist in farm transportation, and the best way to supply them.

How well we have succeeded you can judge when you know that more than 40 per cent. of Studebaker cars are sold annually to farmers.

On Studebaker cars you pay only one profit, as we have said, and the money we save by our complete and thorough manufacturing and huge production goes into the cars themselves to make them better—

To make them last longer; to make them lighter yet stronger; to make them run farther on a gallon of gasoline and oil and on a set of tires.

One thing that adds excess value and life to a Studebaker car is the special steels we use, made to our own specifications especially for Studebaker cars.

Another is the scientific heat treatment of vital parts, like gears, axles, axle shafts, etc., which makes them stronger, longer-wearing, and permits lighter weight with increased strength.

A third is the absolute accuracy of our manufacturing processes, and the resulting perfect fit and alignment of parts, and perfect balance of the motor and the entire car, reducing friction and wear to the very lowest point.

Studebaker economy, in both FOUR and SIX, is known the land over.

Studebaker owners have found our cars peculiarly free from the necessity of repairs and frequent adjustment; all parts readily accessible and cared for with the least time and effort.

Ride in a Studebaker car—FOUR or SIX.

Note how it holds the road without weave or side-sway and know that this roadability is the direct result of Studebaker engineering and Studebaker complete manufacturing.

Equal economy, equal quality and equal roadability are not thus combined in any other "Four" or "Six."

Send for the Studebaker Proof Book which tells all about Studebaker manufacturing processes and illustrates them.

STUDEBAKER, Detroit
105 Piquette Avenue

No. 241

Hope Farm Notes

THE SUN SHINES.—When the sun finally chased the rain clouds and fog away it found one field with hay that had been on the ground 10 days. There had been one or more showers each day. We shook out this hay again and again only to have it soaked over and over. When the sun did come it brought a good breeze to help, and we finally tumbled that hay into the barn. The color was poor, but the stock all eat it well. It seems remarkable how much rain hay will stand and still make good feed. After this long experience with wet hay I begin to question whether it is better to leave it in cocks in rainy weather. That seems the general practice, but most of ours was spread out during the rains. I think it dried out quicker and was less inclined to ferment and sour than where it was kept in wet cocks. It looks now like clear weather for a while. No doubt in August we shall be complaining about dry weather. There will now come a great rush to finish haying, save the rye and clean up the weedy crops.

CATTLE BEETS AND CORN.—Our three acres of beets look better than I expected. On last year's potato field rye was seeded last Fall. This Spring, when the rye was shoulder high, it was turned under, and 1,000 pounds to the acre of slaked lime worked in. The potato crop last year was light, and I figured that the fertilizer we used on potatoes would help the beets. The crop started slowly, but is now making good progress. It has been cultivated twice, and now the slow job of hoeing and weeding has begun. In a country like ours where there are many small farms or backyard gardens, hundreds of people keep small flocks of hens and do not provide Winter green feed. Mangels are excellent for this, and there is a good demand for the roots at nearly the price of potatoes.

PRICE OF BEEF.—I got just $19 for that combative heifer. The local butcher could not handle her, but finally there came a trader and after much argument I let the heifer go. The only other thing to do was to keep her until Fall, fatten her, and then slaughter her at home and sell the meat as best we could. All things considered I decided to let her go. In talking with others I conclude that this price was up to the average. In the dairy districts where many cows are turned off, buyers can handle them in droves, and a good fat cow will bring a fair price. In ordinary farming or fruit districts a single cow can rarely be handled to advantage, for the butchers deal in dressed beef and rarely slaughter an animal. A man may kill such a cow and distribute the meat among his neighbors or peddle it out, but that is about all there is to it. You cannot raise a two-year-old heifer or steer in this country for less than $50. Yet some of these fool Congressmen would, if they could, compel us to raise at least two beef animals each year, and then give them away.

OILED ROADS.—Our township or borough has for the past few years used oil on the roads. I have had a number of questions from people who ask the cost of such oiling. Our people used the oil on about five miles of road in a track 12 to 14 feet wide. This required 6,900 gallons of petroleum road oil No. 5, which cost $3.96 per 100 gallons f. o. b. at our station. The cost of application by sprinkler was about $42. This makes a cost of about $63 per mile for the oiling. Our roads are well made and smooth, of stone. The chief object of the oiling is to prevent dust. The oil also, I think, prevents some wear by automobiles. During the driest part of Summer there is practically no dust, and the water runs off freely in wet times. In this section a part of the high land values depends on our roads and the convenience they give to motor parties. It is surprising how these people know the condition of the roads all over this country, and a smooth oiled road becomes the best advertisement for a town or neighborhood. Much the same thing is true of attractive lawns and grounds. With so much travel on our roads neatness pays, for an attractive front yard is sure to hold attention.

LATE PLANTED POTATOES.—I have received a good many notes from people who have tried late planting. I had no idea there was so much of it done.

I notice your remarks in "Hope Farm Notes" about your late potato planting. As you will spray to guard against blight, I predict the success of your experiment. Many years ago—before I knew THE R. N.-Y.—an old neighbor, who was doing some work for me, said he was going to take the Fourth of July for his own garden, among other things, plant some potatoes, a regular practice on his "swamp" garden. Last year I planted about 500 hills on wet land June 21. The seed was whole small potatoes that had been spread in a sunny window since the Spring planting, May 1. They grew and yielded fairly and kept perfectly. July 7, 1914, I planted 200 or more hills, the same way.

I do no spraying except with Paris green for bugs with powder gun. E. L. S.
Massachusetts.

Our late potatoes, planted June 28 and 30, were from six inches to a foot high by July 17. The color is good, but the vines are not very stocky. I have no prediction to make yet. This wet, "muggy" season is supposed to be about the worst thing that can happen to potatoes, but our crop is the best we have ever had thus far.

COLLEGE FARM HELPERS.—Here is a little contribution to the farm help problem which starts a line of thought:

Since then I have had experi nce which might interest you in regard to city help. I had an engineering school vacationer here who wasn't worth half his salt; now have a Harvard junior, who is the finest hired man I could ask for.

I have had various experiences with college boys, both as hired man and employer. It all goes past the college or the training to the man himself. On general principles you would think an engineer ought to make a better farm helper than a literary student, but it doesn't follow. The engineer may be a drone, or so trained that the most he is looking for is "a good time." The boy with a classical training may have ambition and natural industry to carry him through. It is in the man and his bringing up—not in his education.

THE HEN CONTEST.—I have had a number of letters somewhat like the following:

What has become of John H. Robinson and his proposed hen contest?

Mr. Robinson seems to be doing business at the same stand, but I have heard nothing more about the contest. I had a very pleasant letter from Mr. Robinson in which he said that he would not care to enter any of the official contests unless he knew that his hens would be fed and cared for just as he desired. In his paper Mr. Robinson gets after the Hope Farm man with a sharp stick. He seems to think we are slandering the fanciers and the American Poultry Association. Then he says as THE R. N.-Y. is printed every week we can sow four rows of errors to one row of his facts. Now Mr. Robinson need not worry about all these troubles. We are not going to give him or anyone else a lot of free advertising by spreading a bushel of words all around a subject without touching it. There is only one thing to do. We printed the picture of an "ideal" Wyandotte. I don't believe there ever was any such bird, but it is what the "standard" calls for. I claim that a hen shaped like this "ideal" will not excel as an egg layer. Now, if Brother Robinson thinks otherwise let him put a pen of these dumplings into one of the egg-laying contests, and show us. All this baby talk about "slandering" people and "sowing rows of errors" may cause the fanciers to straighten up their tail feathers, but it will never prove that the dumpling Wyandotte is a heavy layer. Brother Robinson may have all the word contests to himself. If he wants to prove anything let him come up to the rack with a pen of his dumplings.

I know that rye is your great hobby as a cover crop. I wonder what you would do with the following two-year-old apple orchard? It contains about five acres. I have kept it well harrowed up to this writing. Next year I wish to plant one-half of it in potatoes and the other half in corn. What cover crop shall I put in now? The land is inclined to be a little sour. H. M. E.
Connecticut.

As this land is sour I should sow rye and Dwarf Essex rape as the surest thing I know of. I doubt if Hairy vetch would amount to much the first season of sowing. Rye does better on a sour soil than any crop I have tried. I should sow a bushel of rye and three pounds of rape to the acre. It will be necessary to make two seedings—the rye first and then the rape—cover with a harrow or brush drag. The rape will mostly kill out in Winter. Plow the rye in early for the potatoes. For the corn let the rye grow till it heads, then plow under and use about 500 pounds of lime per acre. Now do not say that the Hope Farm man advises rye and rape for *all* situations. I do not. Each case requires some special study. There is no single combination for all. In this particular case I think rye and rape will pay. H. W. C.

Apple Pomace Around Trees.

I PUT a heavy coat of apple pomace under apple trees, with the immediate effect of apparently killing the grass and weeds, which is what I hoped for. But in two or three years a rank growth of Orchard grass came in, so that I knew that while the trees were helped for a time, the soil was not injured for other crops. G. S. P.
Maine.

We have explained how these vegetable acids in pomace or forest leaves act. Before decay they act to kill out most growing plants. Many of them, as decay proceeds, pass off as gases, and the leaves contain so much lime that after these acids disappear the soil actually becomes sweeter. The seeds of the Orchard grass were probably in the soil, and they sprouted and grew as the condition became favorable. Fresh sawdust would in time act much the same way, but it decays so slowly that the soil would be injured for some years.

OPENING a bazaar in Devonshire, Mrs. Dale-Doolette told a significant anecdote: "Last year I asked a man whom I met what he felt chiefly interested in. He answered, 'I am throwing my whole soul into pigs.'"—Woman's Journal.

WILLIS (in the cemetery): "This can't be Hardupp's grave. The inscripton reads 'Mrs. Hardupp.'" Gillis: "Yes, but you see he had his tombstone, like his other things, put in his wife's name."—Puck.

WHEN you write advertisers mention THE R. N.-Y. and you'll get a quick reply and a "square deal." See guarantee editorial page.

KODAK

Everywhere on the Farm

there are fascinating subjects for your Kodak—the harvest scene, old "Shep" driving home the cows, the calf butting his pail of milk, the intimate home scenes of everyday life and the good times with the children and even home portraits—all of these have a value that cannot be estimated. Every picture tells a story that you will always be glad to recall.

Kodaks $6.00 and up.
Brownies $1.00 to $12.00.

Ask your dealer for illustrated catalogue, or we will mail it free.

E. Frank Coe Fertilizers

1857 THE BUSINESS FARMERS' STANDARD FOR OVER FIFTY-FIVE YEARS 1914

Are You Planning to Increase or Cut Down Your Success?

WITH the present prospect of bountiful harvests this fall should come a full realization of the enormous stores of plant food consumed by crops in their growing.

Successful Crops Can Be Maintained Only By the Same Forces or Elements That Have Been Growing Your Good Crops in the Past

To insure better crops in the future and to guard against so-called "soil-exhaustion" you should use an abundance of the right kinds of plant foods for late summer and fall seeding.

No doubt your chief interest is in profits from your farm and the experience of fifty-seven years has shown thousands of farmers that **E. FRANK COE FERTILIZERS** are real profit makers. Are you not willing to have these superior fertilizers prove this on your farm?

It will pay you handsomely to give especial attention to your grass seeding which should be done not later than September 1st, in order to get the best results.

When actual figures show a net gain of $33.33 per acre, per year as the result of proper fertilization of hay fields, do you not think it is well worth while?

You ought to have a copy of our booklet, **"Seeding to Grass and Clover,"** written by one of the greatest farm workers in the country. The illustrations relative to plowing ought to be worth $100.00 to any farmer.

A copy of this booklet is yours for the asking if you will mention the name of your farm paper when you write.

THE COE-MORTIMER COMPANY, 51 Chambers St., New York
Business Established 1857

Ruralisms

Apple Trees Fail to Bear.

CAN you tell me what I can do to make perfectly healthy apple trees bear? They are among others that bear year after year abundantly, but seem to refrain, although they are in excellent condition. G. W. P.
Massachusetts.

Such trees can often be forced into bearing by girdling them in early Summer. I fear it is too late this year to do this to be effective for the next crop, and it might injure the trees if done now or later. By this I mean to peel out a ring of bark about two inches wide all around the trunk of each unproductive tree. But this should be done late in May or in June, so that there will be time to form fruit buds. It might do good and would do no harm now to cut right through the bark, but not peel any of it out.

H. E. VAN DEMAN.

Mulch for Ginseng.

I WOULD like some information on what to use for making mulch for a ginseng bed. My experience is that it would require a more rich and substantial mulch than for culture of most other plants. C. J. R.
Pennsylvania.

The best mulch that I have ever tried or heard of for ginseng beds is old sawdust that has gone through the fermenting process. New sawdust has acids in it that will injure the ginseng. About two inches in depth is sufficient for keeping down most of the weeds and the ground moist. The soil should be made very rich in humus with old wood mold and coarse, rotted manure before planting the roots. A heavy dose of bone meal and acid phosphate is very beneficial also.

H. E. VAN DEMAN.

Grafting Chestnuts.

WILL you give me some information regarding the grafting of chestnut trees? I can successfully graft and bud any kind of fruit tree, but fail on the chestnut. I have a piece of land that has had the timber cut off, and there are lots of chestnut stumps growing sprouts five to 10 feet high. Can those sprouts be successfully grafted with some of our large varieties, and how and when should this work be done? D. S. M.
Pennsylvania.

Chestnut trees can be grafted very successfully if the proper way is followed, although it is not done so easily as with fruit trees. It has been done successfully in the ordinary way and at the same season as ordinary grafting, but far better results have followed doing it after growth has started in late Spring time. The scions should be cut before there is the slightest chance of the buds starting to swell, and be stored where they will be cool and moist. When the trees to be grafted have begun to start the grafting should be begun. At first the regular cleft and tongue or splice methods should be followed. Later, when the bark will peel easily, the bark graft is the proper method to use. This is done by trimming the scion all from one side, making a long, slim point. The wood is not split, but the bark slit on the stub and the point of the scion introduced in top of this slit, then forced down under the bark the full length of the wedge or trimmed surface. The scion so set should be tied firmly in place with a cotton string or raffia and the wound waxed over completely. It is a great benefit to the grafts to cover them wtih paper bags, by inverting one over each graft and tying a string over the lower part to hold it in place. This keeps the moisture from escaping while the union is taking place. After the growth is well started on the graft the paper bag should be removed or torn open at the top so the sprouts may have egress.

By applying to the State Experiment Station officials at State College, or to the Department of Agriculture at Harrisburg, a publication can be obtained that gives information about chestnut culture and grafting. H. E. V. D.

Tomatoes Not Setting Fruit.

WILL you explain the following? I am growing Ponderosa tomatoes; plants are 3½ feet high and very strong, and for about the last three weeks in bloom, but up to date there is no sign of any fruit setting on. The flowers, after blooming, seem to dry up and fall off, leaving the bare stem. Is there such a thing as male and female plants or flowers in tomatoes, as I can recognize only one kind of flowers on the bushes. The same happened last year with pole beans; plants grew up to be seven feet high, but failed to bloom. W. H.
Long Island, N. Y.

This question is rather difficult to answer, as the conditions of the soil and the weather they have been subjected to have not been stated. All tomatoes have bi-sexual blooms—that is, the blooms have both the male and female organs, and are almost invariably self-pollenizing. When the flower fails from any cause to develop stamens or pollen-bearing organs, fecundity fails to take place, and the flower withers and drops from the stems. This condition can be caused by one or more of several conditions the plant is subjected to, the most common of which is over-stimulation of the plant. If the soil is very rich in nitrogen the plant will be over-stimulated, resulting in a rank growth of vine and the setting of very little if any fruits until late in the season, when it will have used up the oversupply of nitrogen. By this time the plant will have nearly reached its normal size and the food supply available will be a more evenly balanced ration, when the plant will, as as a rule, set an abundance of fruit. Continuous wet, cloudy or foggy weather will also prove detrimental to a greater or lesser extent, and sometimes prevent the pollenizing of the blooms entirely, which, of course, will prevent the setting of fruits; but this condition is remedied as soon as the weather clears, and is therefore only temporary. Too much shade will also be detrimental to the setting and development of fruits, but when the plants are situated where they have the benefit of the full light of the sun, and fail to set any fruit, it is pretty certain they are over-stimulated. Tomatoes do not require a strong soil, and will always do better in a rather poor soil than in a strong soil.

Jarring the bloom with a small stick will sometimes prove helpful, provided there is a proper development of the blooms. The jarring of the blooms should be done between the hours of 10 and two o'clock. K.

Grapes Fail to Bear.

I BOUGHT six vines each from a reputable firm in Fall of 1911, Worden, Green's Early and Salem, said to be two years old. They were planted in November. In October, 1912, they were replanted and again showed nice shoots during the next Summer, 1913. These vines received no care during the Spring and Summer of 1913, but in the Fall were given a lot of rotted manure, placed over the roots. They look very fine and healthy, but only two vines show any evidence of bearing, a single bunch each. No insects, bugs, etc, have been at them. The ground has been cultivated regularly, the vines have had good care, are placed in a sunny position, planted north to south and have the sunshine all day long. R. R.

As a rule grapes do not bear much fruit until the third and in some localities the fourth year after transplanting to vineyard. I am of the opinion that these vines would have fruited satisfactorily this year, if they had not been removed to another location in 1912, provided the soil and climatic conditions were congenial to them and the vines not over stimulated by the application of too much nitrogenous manure. I think they will fruit satisfactorily next year.

A large and thrifty growth of vine is no sure indication that any variety of grape will bear satisfactorily or that they will produce any fruit at all. Some varieties are very capricious, bearing fruit only in certain localities specially suited to their requirements, this is partiealarly true of nearly all the Rogers hybrids, of which the Salem is one. Out of 30 or more varieties originated by Mr. Rogers, near Salem, Mass., only three or four of them proved of any real commercial value, and the territory in which they will succeed is quite limited. Green's Early, Brighton, Niagara and a number of others that are favorites in certain sections of the hill country in New York and Pennsylvania are utterly worthless in other sections of those States. In Western Pennsylvania, about 35 years ago, my father tested about all the varieties of grapes introduced up to that time, including all the Rogers hybrids. The only varieties that gave satisfactory crops were the Concord, Hartford, Ives, Martha, Isabella, and Blackhawk. The Brighton, and all the Rogers hybrids, were partial or total failures at fruiting, the vines would make a very strong growth and most of the sorts would set more or less fruit (some failing to set fruit at all) but they were so subject to mildew that we very seldom got enough ripe fruit to test them for flavor. The Worden, like its parent the Concord, succeeds well almost everywhere and in almost all kinds of soils, and when not over-supplied with nitrogen is a dependable cropper.

It might be well to withhold manures of all kinds from these vines for the next year, not applying any until the Fall of 1915—or Spring of 1916, as the strong growth the vines are making this season indicates they are well supplied with nitrogenous matter, perhaps with more than they should have. I think the Worden will prove suitable to your section and will bear a good crop next year, but Green's Early and Salem are rather uncertain, if the soil and climatic conditions are not to their exact liking. If conditions should prove to their liking they will reward you with large crops of most delicious fruit. If your soil is naturally rich, I would advise using manures very sparingly until the vines have reached some age. Coarse ground raw bone will give much better results, and can be applied in liberal quantities around the vines without danger of stimulating them to make abnormal wood growth. It will require at least another year, and perhaps two, to test these vines out thoroughly, but next year should show partly nearly what you can expect of them. K.

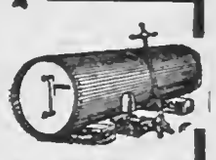
Through this part of the State adjacent to the State's capital, the peach crop promises to be large. I never had better prospects for a fine crop. We are well on with thriving fruit, and the fruit is very fine for this date. We have our first ripe peaches now. An early variety never worth very much anywhere, but its a peach for the folks that can't wait very well till good peaches come in. Our first really good peach is Carman, which ripen in this section about the middle of August. The usual varieties follow in regular order, and end up in September. We grow the largest, finest and best the world produces.
Pennsylvania. E. C. B.

AUNT Eliza came up the walk and said to her small nephew: "Good morning, Willie. Is your mother in?" "Sure she's in," replied Willie truculently. "D'yu s'pose I'd be workin' in the garden on Saturday morning if she wasn't?" —Ladies' Home Journal.

GROUND LIMESTONE
FOR
SOIL IMPROVEMENT
ALFALFA SEASON NOW APPROACHING — *ORDER EARLY*
THE STEARNS LIME COMPANY
DANBURY, CONN.
PIONEER IN NEW ENGLAND

WHERE ROCK PHOSPHATE PAID
VIRGINIA:—"I used 400 pounds and secured ½ ton increase in Alfalfa."
INDIANA:—"My clover hay and seed crop was increased 1 T. and 1½ bu. per acre by Daybreak Rock Phosphate."
ILLINOIS:—"At the rate of 800 pounds per acre I secured the first year an increase of 25 bu. of corn."
MISSISSIPPI:—"Daybreak Rock Phosphate made an increase of 10 bu. corn."
Daybreak Rock Phosphate is paying in 37 States. It will pay you to write us for booklet and prices.
FEDERAL CHEMICAL CO.
GROUND ROCK DEPT.
No. 30 W. Main St., Columbia, Tenn.

CORN HARVESTER with binder attachment, cuts and throws in piles on harvester or winrows. Man and horse cut and shock equal to a corn binder. Sold in every state. Price only $20.00 with fodder binder. J. D. Borne, Haswell, Colo., writes: **"Your corn harvester is all you claim for it; cut, tied and shocked 65 acres milo, cane and corn last year."** Testimonials and catalog free, showing pictures of harvester. Address **PROCESS MFG. CO., Salina, Kans.**

$39.00 BUYS THIS SIMPLEX WATER WORKS SYSTEM


guaranteed to do your work. Sixty days free trial. Other sizes as cheap. Pumps, motors and engines. Write for our New Way Selling Plan No. 25

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York

HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 75 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

HATS off for those American Leghorns in the Storrs egg-laying contest! After a long, uphill race they are within striking distance of the English Wyandottes, and with next week's record we expect to see them ahead. This may be called a double victory for American breeding and American sour milk, for this pen of birds has received sour milk as food almost from the shell. Polo games and yacht races may provide sport for millionaires, or rich idlers may strike at golf or tennis balls, but they should all take a back seat when the American hen lays her way up to the front. Hurrah for Mrs. A. Leghorn—a nest frequenter in white!

*

BUSINESS men in Saskatoon, Saskatchewan Territory, realized that their future depended upon the prosperity of farmers who traded in that town. Most of these farmers were growing wheat. This meant a one-crop income, dependent upon blight and frost, with half the year idle. The town was using butter brought all the way from New Zealand, while all around were rich pasture and hay lands. So a group of business men organized a creamery and began to encourage dairying. For a time it was slow work, but now, after two years, there is no more New Zealand butter sold in town, and the first carload has been shipped away. The farmers are receiving something like $16,000 per month for their milk. Neither the farmers nor the business men alone could have carried out this plan. By working together there has been a mutual advantage.

*

NEARLY every week we have letters from farmers who say they have a good supply of large, white eggs which they want to sell to some special customer. Readers have heard that certain hotels or high-class restaurants pay enormous prices. These men are sometimes disappointed in dealing with this high-class trade. They find such patrons very particular and very critical regarding size, color and quality. A farmer must, of course, understand that the buyer is the one to be satisfied, and that there is no use trying to make him take what does not suit him. Another reason why this kind of trade prefers to deal with middlemen is that very few producers can guarantee a definite number of eggs each week in the year. The supply will be intermittent, and this is just what the hotel *does not want*. When they buy from a city dealer they can hold him personally responsible for quality.

*

WE have received several letters from insurance men who attempt to argue that the new compensation law in New York makes farmers liable for accidents to their employees. We feel confident that there is nothing to this. The law expressly excludes farm labor and domestic servants from its operations, and also states that "employment" includes employment only in a trade, business or occupation carried on by the employer for pecuniary gain. Many good lawyers have been consulted regarding this, and they agree that farm laborers and domestic servants are not affected by this law. They stand in the same relation to their employer as they did before the law was passed. Under previous laws a farmer might, under some circumstances, be liable for an injury sustained by his hired man, but the chance for such liability would be remote. Of course all laws must be tested in the courts before a final decision is reached, but the best legal advice we can get is that farmers are not liable under this law.

I NOTE your reference to the field meeting of the New Jersey State Horticultural Society. Are strangers tolerated at such meetings? A friend and myself are much interested in apple-growing, and should like very much to see the Barclay orchard and hear the talks on the occasion of the meeting. A. C.

Tolerated? Strangers are made welcome at every true farmers' meeting. Go by all means. You will find a company of kindly hospitable farmers and fruit growers ready to tell you what they can. We grant that sometimes meetings are held in the name of agriculture by gentlemen who do not want practical farmers around. Farmers will dominate this field meeting, and you will be made to feel at home. Remember the date—August 5 at the farm of John H. Barclay, Cranbury, N. J.

*

NO man ever "tampered with nature's balance" without regretting it. You may try it with your own body or your farm, or with a nation. The result is the same. A curious instance of this comes from India, where the concerted campaign against tigers has resulted in an enormous increase of wild pigs—which do great damage to crops.

"The native farmers are forced to watch their fields carefully at an increased expense. This damage and increased expense must be t ken into consideration in fixing the new land tax, and thus the strange situation exists that by the destruction of the tigers the farmers may be out of pocket."

Charles Darwin pointed out the economic relations between old maids, cats and field mice. A war of extermination against moles and skunks would rid us of some annoyance, but bring about a plague of white grubs. Even mosquitoes and rats have their places in nature's economy.

*

RECENTLY 10 tons of fish were thrown into the Delaware River and thousands of bunches of bananas were similarly disposed of to avert a break in the market. This wanton waste of food that people are clamoring for will have no excuse for its practice, for the express company's order bureau will find a market in towns and villages remote from this market. This was accomplished in a recent glut when fish, sold in the Maryland peninsula at two cents a pound, was distributed among dealers up and down the State, who sold it at five cents.

That is taken from an article in the daily papers on the system which the express companies are now developing. Parcel post has spurred the express companies on to find markets for farm produce. Why did they wait until the people pulled their fingers away from the throat of Congress? If they had started any such scheme 20 years ago, when there was great need of it, the fight for parcel post would have been held up, and none of the present powerful movements for control of government utilities would have become strong enough to attract general attention. It was the hateful, dog-in-the-manger policy of the express companies which made parcel post possible. These companies are now trying to please and help the public. This growth in sentiment from Vanderbilt's reported opinion of that same public is good evidence of what may happen when the people learn how to get what belongs to them.

*

YOU talk about the use of cover crops. Why not let the weeds grow instead of sowing expensive seed? Some of these weeds will provide as much bulk to plow under as the crops you speak of.
J. B. H.

We keep talking "cover crops" because we know what such crops and lime have done for our own soil. When we know that nature will in this way make us a present of the equivalent of six tons or more of manure per acre and spread it for us we want to pass along a good thing. There are some cases where the weeds make a good cover crop. We have two fields where this has been tried for some years. The objections to letting the weeds grow are several. In most of our crops we must have clean culture. When weeds go to seed the labor of keeping crops clean is doubted. A cover crop of rye and vetch or rape smother out the weeds and thus helps clean culture. The broad-leaved weeds take more moisture from the soil than the narrow-leaved rye or vetch, and in ordinary seasons give the cultivated crops a better chance to mature. The weeds die at first, and thus provide no living crop to hold the soil through the Fall and Winter and give no live crop in the Spring. There is a heavy loss of nitrates from the soil in November at the North, and through the Winter at the South. The living cover crop saves this loss and also, in the Spring, gives a live crop to plow under which we believe is better for the soil. The cover crop also adds more organic matter. These and other reasons have convinced us that it is more profitable to sow a cover crop rather than to let the weeds grow. No one argues that it is better to let the soil lie bare through the Fall. In some orchards it may be better to let the weeds grow after cultivation is done. This saves the cost of seed and seeding, supplies a fair amount of organic matter, and makes easier working or plowing in the following Spring, since the weeds die during Winter.

SOME of the farmers on the Pacific Coast are much excited over the imports of cheap eggs under the new tariff. Eggs are now free, and millions of them are being brought from China and other Asiatic countries. One of our Washington readers tells the following story:

A prominent citizen of Portland, Ore., purchased a setting of the freshest of these eggs he could get, put them under a hen. Out of the entire setting only two of them hatched, and instead of being chickens they were sea gulls. W. H. P.

Unless this man is careful our wonderful laws will go still further and he will be prosecuted for importing game or plumage birds!

*

IN New Jersey every railroad company organized under the laws of that State, must erect and maintain fences on the side of its road the height and strength of the division fences which are required by law. One of our readers has been for some time trying to get the Pennsylvania Railroad to build a fence where the railroad property adjoins his farm. The company claims that their deed does not specify that they shall build any fence, and neither does the deed of the owner. The company wants this farmer to make them a proposition. On application to the Public Utilities Commission of New Jersey, we are informed that this Commission would not pass upon the question until a definite case is brought before it. Under the circumstances our advice to such a farmer is to make a direct complain to the Public Utilities Commission at Trenton. Make this in the form of a letter, and send a copy of this letter to the railroad company. The Commission will then set a date for an informal hearing, at which both the farm and the railroad people can be represented, and the facts brought out to settle the matter definitely.

*

A FAVORITE and impressive text from the Scriptures is:

"Take heed how ye hear!"

Hardly a day passes without a practical illustration of the danger in jumping at conclusions. In a recent case a farmer wanted to buy some purebred cattle. He bargained with a reputable breeder who stated in his circular that his farm was headquarters for stock bred on his neighbor's place. At the head of this breeder's stationery was a statement that the farm had been breeding stock 25 years or more, and that all animals were of this long-kept strain or family. In the bargain between farmer and breeder nothing was said about the cattle all being from this particular family. When the papers came it was found that the cattle were from the other farm—well bred, but not of this particular strain. Then the farmer claimed that he had been wronged because he said he had been promised a certain breeding which he never received. It seems that he read the heading on that stationery and assumed that it meant a guarantee. It was nothing of the sort, and was never intended to be. There are many cases like this where a man assumes on his own responsibility that words have a certain meaning which they were never intended to carry. This assumption of meaning makes no end of trouble when a question of fact arises. *"Take heed how ye hear!"*

BREVITIES.

THE apple rust disease cannot live in a locality where all the cedars are cut down.

EVEN the ancient Kingdom of Libia has its experiment station and agricultural expert.

GERMANY is to have a system of strike insurance, developed by employers' protective associations.

SOUTH AMERICA imports $18,000,000 worth of canned goods, yet the United States contributes only about $2,500,000—mostly salmon. Why can't we sell more cans?

SOME of our farmers complain that the scientific men may take a "vacation" just when they are most needed in the field. In business the time for vacation is when work is slack, or when there is least to do.

AN American farming colony has been started in the Philippines. It will start with about 100 colonists. The men are Americans mostly married to Filipino women. The government will help these colonists with small loans.

A GREAT many of the legal questions sent to us refer to differences over line fences. Recent reports from a locality in West Virginia tell of a feud arising from this cause, which resulted in the death of three men. It is wise to fix fences before they can lead to long-drawn-out disputes.

HERE is another one from New Jersey. The State has one mile of railroad to every three square miles of territory. This is the largest proportion of railroad mileage of any State in the country. As a consequence of this, New Jersey has a great number of railroad fires. It used to be said that 99 per cent. of these fires started from red-hot cinders puffed out through the locomotive. It is now claimed that this is too rough on the locomotive, and that many of these fires really start from glowing cigarettes which are thrown out through the window from the smoking cars as the trains rush on. Here is another bill of damage against the cigarette fiend.

LAND BANK ASSOCIATION FORMED.

THE work of organizing the Land Bank of the State of New York is progressing most favorably. Ten associations, by action of their board of directors, have enrolled themselves already. The total resources of the 10 enrolled associations is $4,000,000, and the subscribed capital, $42,000. Four of the 10 associations are directly represented on the organization committee. A number of associations have notified the committee that they will come in, but they are not enrolled until the Board of Directors has authorized the purchase of shares in the Land Bank, subject to ratification by by-law. This progress indicates that the Land Bank will be organized during the Fall. So far there is but one strictly farmers' association organized. This is the association formed recently by the Jewish farmers at Centreville, in Sullivan County.

THE R. N.-Y. office force and staff, however, are to have a local land bank. At the first suggestion 40 persons signified their intention to become members, and subscribed for shares to the matured value of $40,000. Its proposed charter and by-laws have been sent to the Superintendent of Banks, at Albany, N. Y., for approval. As soon as these are approved, a meeting will be held, and the Association will then be ready to receive the first dues on the shares. The Association may issue four kinds of shares, viz.: 1. Installment shares on which dues of 50 cents per share per month, or $1.50 per quarter, will be paid. 2. Paving shares, the dues on which may be paid in such amounts and at such times as the member may elect. 3. Accumulated shares on which the member will pay down $50 or more at the time of issue, and the dividends will be added until the share matures at $100. 4. Income shares, on which a payment of the face value of $100 will be paid at the time of issue; and the dividends paid semi-annually in cash. The funds will be loaned to members on first mortgage, on real estate situated within a radius of 50 miles from the place of business of the association. Loans may also be made to members on the security of his or her stock. The board of directors may accept membership anywhere; and loans may be made on shares of the association anywhere, but loans on real estate cannot be made outside of a radius of 50 miles from the principal office of the association, which will be in New York City.

This association will probably become a charter member of the Land Bank of the State of New York. Both of these new associations represent agricultural interests, and it is expected that several others will be organized and will become charter members of the Land Bank when organized towards the end of the year.

Any reader of THE R. N.-Y. is eligible to become a member of this association for saving purposes, and all members within 50 miles of New York will be eligible for loans. J. J. D.

A 35-CENT DOLLAR CONFERENCE.

THE 35-cent dollar was very much in evidence at the Co-operative Conference held at Utica, N. Y., on July 22. The conference was under the direction of Agricultural Commissioner Huson, and its object was to bring those interested in co-operative buying and selling together for a general discussion and organization. Gov. Glynn delivered an address and there were short talks and discussions by a large number of prominent men.

The spirit of the conference was excellent. All who attended were thoroughly convinced that the time has come for the consumer, through co-operative work, to come closer to the producer, and thus cut out a large share of the waste which now goes to the useless middleman. These shrewd and practical men understand of course that in our present scheme of distribution it is impossible to eliminate all the handlers and carriers who stand between food production and consumption. They also understand that there has grown up a system which embraces a large number of useless handlers, so that the cost of their handling is taken out of the share which ought to go to the producer. It is a big job to rearrange the present system of distribution, but this conference shows that thoughtful men now realize the significance of the movement and it is sure to develop and grow under the right direction.

All sorts of interests were represented at this conference. There were practical farmers who for years had been producing food as individuals, now thoroughly convinced that all these years they have obtained not more than 35 cents of the consumer's dollar. At the other extreme there were men who frankly admitted that they were not producers, but were consumers pure and simple. Yet they realized the great tax that they were paying for their supplies and the small proportion of their money which finally finds its way into the hands of the farmers. All sorts of plans were talked over, such as co-operative societies, advertising, and a dozen other methods which business men in other lines of work have successfully adopted. The whole spirit of the conference was hopeful, and without question it will lead to good results. The most hopeful and the most significant thing connected with it was the fact that no one any longer questions the existence of this 35-cent dollar, or the share which the farmer receives on the average for the price that his produce finally costs to the consumer. This conference has brought that question up into the minds of many who did not understand it before. This is the fundamental principle of all efforts to co-operate and give the producers a fairer share.

We shall give from time to time studies of what was developed in the discussions at this conference. It is new evidence of the great movement which is slowly gathering force to bring producers together in a business proposition which is destined to revolutionize our present system of distribution.

New York State News.

THE NEW EMPLOYMENT BUREAU.—On August 1 to be exact, the first of a chain of employment bureaus will be opened for business under the terms of a bill passed at the last session of the Legislature. Much is expected of the new bureau and it is to be hoped that the expectations may be realized. The thing is to bring the man and the job together and this the State proposes to do without cost to either employer or employe. Theoretically the plan looks good. If a machinist in Rochester needs men, and if the bureau has a list of men on its records who are capable of filling the need, then it is an easy matter to bring the two together. No fees are charged to anyone. Indeed, if it be found that anyone accepts a fee for any service he may render under the law, he will lay himself open to a fine of $500 or less or imprisonment for six months or less. Perhaps the greatest assistance that this bureau can render will be in the investigation of the causes of unemployment and applying remedies therefor. Each of the State employment offices will have an advisory board to be composed of representative employers and employes and there shall be an equality of voting power among them notwithstanding the absence of any member. The new bureau has a great big work to do. It will be watched with great interest.

ARMY WORMS AND HOPPERS.—The plagues seem to be descending upon us these last few days. No sooner had the grasshoppers got well under way in their invasion of certain localities of the State, than they were followed or "aided and abetted" in their work of destruction by the army worm. The fight is on. The Department of Agriculture and the Experiment Station and the Farm Bureaus, are all taking up the cudgel against these destructive enemies of the farmer with varying success. But the "poison squads" will win out in the end. The grasshoppers have spread over a much larger section of the State than they had covered last week. Both pests have cut down the growing crops in wide swaths. Farmers can aid the department in its fight by using the poisoned bait made as follows: "Fifty pounds of bran, thoroughly mixed while dry with 2½ pounds of paris green; add five quarts of cheap molasses diluted with about nine gallons of water and juice of eight lemons. Then chop the lemons up fine, rind and all, and mix with the above. This is to be sowed broadcast near where the pest will be attracted by it. In the case of army worms, a furrow can be plowed toward the insects, and when they gather in the trenches they can be crushed."

FARM SURVEYS IN GENESEE.—H. F. Dixon, a farm survey expert from the U. S. Department of Agriculture, is conducting farm surveys in Genesee and Madison counties, assisted by Director Burritt of the State Farm Bureau Department and several county agents. Over 50 farms will be surveyed in each of these counties, kinds of crops raised, methods of farming and many other particulars will be investigated. It will be a good opportunity also for farmers to discuss their problems with these experts.

STATE SEALER IN NEW ROLE.—It may not be known to many of our readers that a law was passed by the last Legislature making any person guilty of a misdemeanor who advertises in a newspaper, circular or form letter or makes any statement of fact as to the quantity, quality or value of goods or articles he has to sell, "which is untrue or calculated to mislead." State Sealer Farrell is now "watching out" for such advertisements and is reported as having some very good material to work upon already. He had some "warranted all-wool blankets" that were advertised, sent to a chemist who analyzed them and found 51 per cent. cotton. The State Sealer will need a vacation after he gets all the evidence in these cases.

FARM HANDS NOT UNDER NEW LAW.—Although farmers are specifically exempt from the provisions of the new workman's compensation law, yet there has been some uncertainty as to whether teamsters on highways and men employed in teaming on farms, came within the purview of the statute. The Compensation Commission says no. Therefore it is not necessary for farmers employing them to be insured against loss from any injury which the teamsters may receive. It is held that the relation of the teamster to the farmer for whom he works is not unlike that existing between the artisan and the private householder who may be employing him to make repairs to his domicile. We wouldn't wonder if the Compensation Commission would have some trouble with this feature of the new law when they come to adjudicate differences of opinion in the matter.

TREE AGENT LOSES AGAIN.—It will be remembered that early in the year the case of Bert Walton of Indianapolis, Ind., against James A. Pettibone of Alexander, N. Y., was tried in justice's court at Batavia and that the jury found no cause of action. Plaintiff had sued to recover $25, the purchase price of 1,000 Catalpa speciosa seedlings. Last week the case was up in county court, to which appeal had been taken, and the decision of the lower court was affirmed. The defense was "fraudulent representations." Hence, defendant refused to accept the trees. It is said that the case will now be taken to the Appellate Court by Walton. He had brought suit against several farmers in Genesee, Wyoming and Erie Counties who had repudiated the contract on the same grounds as did Pettibone and the Pettibone case is considered a test case in the matter.

HUDSON RIVER VALLEY FRUITS.—The Valley has just closed, or is closing, a most auspicious season in sour cherries, red berries and currants. Growers have had a shortage in crates, baskets and cups which at one time threatened to be quite serious. At Germantown, on the east side of the river, this was particularly true. A car arrived with 3,000 baskets and within three hours all were taken and some growers had to get along with 200 or 300 where they needed 1,000. From this town it is estimated that about 40,000 baskets of sweet cherries, 260,000 of the Montmorencies and 100,000 of Morellos, have been shipped, making a grand total of about 400,000 for this station alone. The sale averaged about 35 cents per basket according to reports. In Ulster County on the other side of the river, red berries, cherries and currants were of immense quantity. The currant crop is said to have been the best about ever known in the Highland district. There will be no peaches worth speaking of in this (Ulster) County. The grape crop will be the largest in years, if nothing prevents in the line of damage to which the crop may be exposed. A local grape juice factory will take about 50 per cent. of the crop.

CONVICT LABOR AGAIN.—The first permanent camp of convict laborers has been established in the Catskill Mountains, for work on the highways. Twenty men from Sing Sing are there and as many more will follow. It is said that the men work without restrictions, almost, leave and return to camp at will except during working and sleeping hours. A guard is with them but is said not to be armed. J. W. D.

Foreign Wheat Prospects.

A CONSIDERABLE proportion of the foreign wheat has not yet been harvested but from reports available it appears that the world crop of Winter wheat will be under normal. Winter wheat constitutes about three-fourths of the entire supply; and the Southern Hemisphere crops harvested last Spring were more than 100,000,000 bushels short of previous year. Only one country of Europe, Russia, will have more Winter wheat than last year. Austria-Hungary is expected to be 18,000,000 bushels short, and Italy nearly 35,000,000 bushels under. Taking everything into consideration there is no apparent warrant for ruinously low prices to the producers of our 1914 Winter wheat.

Government Crop Report.

WINTER wheat thrashing is under way with good yields, except in parts of Nebraska. In North Dakota Spring wheat conditions are the best in several years. Minnesota and South Dakota have considerable black rust.

Early planted corn in the southern part of the belt was greatly damaged by drought. Later plantings promise well. In Iowa, Kansas and Nebraska the outlook is favorable, and has improved in the Ohio Valley and eastward.

Haying is about completed, the crop being good in the northern, but poor in the southern sections. The tobacco plant is doing well, though there is some trouble from root rot in Wisconsin and drought in Tennessee and Kentucky.

The situation is considerably improved in the eastern and central parts of the cotton district. In the western part great damage from drought and excessive heat is noted. Garden truck conditions in the South and Atlantic States are improved. Harvest in the New England and Middle States has been hindered by rains and considerable injury done to grain and hay.

Canadian Fruit Report.

THE Canadian Commissioner of Agriculture gives the following report of conditions in the Dominion:

NEW BRUNSWICK.—The apple crop promises 70 per cent., a few orchards injured by frost. Scab showing very little. Summer and Fall varieties heavier than Winter. Size and quality good. Raspberries promising well.

NOVA SCOTIA.—Weather conditions favorable. Very little spot showing. Apple crop will be, at most, one million barrels. Spy, King, Russet, Wagener, Bellefleur, Baldwin and Ribston leading. Nonpareil, Bleuheim, Fallawater, Stark, Gravenstein and Ben Davis light. Crop last year, 650,000 barrels.

QUEBEC.—Most sections looking well. Fameuse and McIntosh dropped heavily, but sufficient left on trees for good crop. Cherries heavy crop. Bush fruits good.

ONTARIO—LAMBTON.—Apple crop 40 per cent. above 1913, and 15 per cent. below 1912. Weather has been hot and dry for six weeks with sufficient drop to prevent thinning. Favorable showers this week, and well sprayed orchards will have a good commercial crop of clean fruit. Plums and pears fair to good, but much lighter than last year. Grapes promise a good crop.

NORFOLK.—Crop one-third heavier than 1913, and one-third lighter than 1912. Fungus prevalent but quality is good in orchards that have been well sprayed.

HURON.—Crop about 25 per cent. heavier than 1913, in spite of heavy drop. Quality will be good. Plums light.

COUNTIES NORTH OF LAKE ONTARIO.—Prospects not so good as expected. Drop has been heavy. Crop will run about same as last year, or about 25 per cent. less than 1912. Fruit well distributed and all trees bearing. Weather conditions fair.

OKANAGAN VALLEY.—Long dry spell was broken by rain. Quality of apple crop excellent. Total crop will approximate 1,000 cars, which is equal to the crop of 1912 and 25 per cent. greater than 1913, with Wealthy, Jonathan, Wagener and McIntosh heaviest. Pears, 20 per cent. increase over 1913. Tomato acreage increased 25 per cent. Peaches a fair crop, totalling 50,000 twenty-pound boxes.

Special attention should be given by shippers to the hour at which tender fruits will reach their destination. Practically 75 per cent. of the fruit is sold in Canadian markets before noon, and where fruit is sold by auction after noon, prices are frequently 30 per cent. less than morning prices.

HONEY PACKING.—The Colorado Honey Producers' Association sends out the following statement to guide the members in packing:

"A honey section weighs approximately one ounce, therefore, to grade comb honey according to the Colorado grading rules and have same conform to the requirements of the Federal Net Weight Law, each packer must make sure that no section of Fancy White or Number One weighs less than 13½ ounces, gross. These must be stamped:

"'Net weight not less than 12½ oz.'

"No section of choice must weigh less than 12 ounces, and these must be stamped:

"'Net weight not less than 11 oz.'

"No section of number two honey must weigh less than 11 ounces, and these must be stamped:

"'Net weight not less than 10 oz.'

"The Colorado Honey Producers' Association, Denver, Colorado."

Woman and the Home

From Day to Day

A Dakota Wheat Field.

Like liquid gold the wheat field lies,
A marvel of yellow and russet and green,
That ripples and runs, that floats and flies,
With subtle shadows the change, the sheen
That plays in the golden hair of a girl—
A ripple of amber—a flare
Of light sweeping after—a curl
In the hollows like swirling feet
Of fairy waltzers, the colors run
To the western sun
Through the deeps of the ripening wheat.

Proud as the fleckless, soaring sky,
Mysterious, fair as the moon-led sea,
The vast plain flames on the dazzled eye
Under the fierce suns alchemy.
The slow hawk stoops
To his prey in the deeps;
The sunflower droops
To the lazy wave; the wind sleeps.
Then all in dazzling links and loops,
A riot of shadow and shine,
A glory of olive and amber and wine,
To the westering sun the colors run
Through the deeps of the ripening wheat.

O glorious land! My western land
Outspread beneath the setting sun.
Once more amid your swells I stand,
And cross your sod lands, dry and dun,
I hear the joeund calls of men
Who sweep amid the ripened grain
With swift, stern reapers, once again.
The evening splendor floods the plain.
The cricket's chime
Makes pauseless rhyme,
And toward the sun
The splendid colors romp and run
Before the wind's feet
In the wheat.

—Hamlin Garland.

*

HERE is a most delicious sherbet or fruit punch: To a pint of red currant juice add the juice of five oranges, three lemons, and a can of grated pineapple. Add cold water enough to dilute to proper strength, sweeten to taste and serve iced. Another delicious beverage is pineapple lemonade. Pare a pineapple, removing the eyes, and shred it fine. Put in a bowl, and add the juice of three lemons. Boil a pound of sugar in a pint of water, removing the scum; pour this syrup over the fruit, and let it stand two hours. Then dilute the mixture with water, and serve iced, straining if preferred.

*

MANY of our readers in this State will, of course, have that bulletin on "Attic Dust and Treasures," issued in the Farm Home Course from Cornell. One of the questions asked in the discussion paper is, "Is your attic warm and dry enough to work in during the Spring, and cool enough to read and work in during the Summer?" There are, of course, attics that answer this description, yet we fear that they are not common. A great many attics are uncomfortable to work in at any season, because of poor light or ventilation. However, two questions are asked in this discussion paper that give ample food for thought. These are as follows:

Would you like to aid in developing in your home community or town some by-industry that farmers' wives and daughters could undertake in addition to their regular work, doing this new work so well that it could be marketed as is the lace, embroidery, and weaving made by women of Deerfield, Massachusetts, of Battle Harbor, Labrador, and of various parts of Denmark and Ireland?

Would the women and the young girls of your community or of your club enjoy working as women used to work in the colonial quilting bees and corn-husking parties on some joint production of your handicraft that would have a market value if properly done?

Those two questions seem to offer a very live subject for discussion among rural women.

*

A POPULAR joke, which contained a sound moral, represented the doctor's wife asking him why he must hurry so excessively when he received a call from Mrs. Brown. "It isn't safe to delay," explained the doctor; "she's got a book on 'What to Do Before the Doctor Comes,' and if I don't hurry she'll do it!" We cannot appreciate this without seeing something of the danger that comes from indiscriminate dosing. Common-sense care of the sick, without professional aid, has helped many of us over hard places. On the other hand, a recent case came under observation where a neuritis patient, sleepless from constant pain, was advised by a friend to take a well-advertized proprietary remedy. The patient did so, without consulting the doctor who had treated her, and found that the medicine made her sleep comfortably, unconscious of her pain. After a week or so she told her doctor of the relief she enjoyed, to learn from him that she was taking a dangerous habit-forming drug, under the mask of curative medicine. Of course, she discarded the cure at once, and being a strong-minded woman she is not likely to lapse from her decision, but think how easily a person of weak will might be led away by such a medical wolf in sheep's clothing! One can learn much of this danger from a Farmers' Bulletin published a few years ago by the Department of Agriculture at Washington, termed "Habit-Forming Drugs."

Seen in New York Shops.

A WONDERFUL evening dress for Summer resort wear was cerise taffeta veiled with a flounced accordion-pleated tunic of cerise tulle. The bodice was a low-cut surplice shape draped with tulle, and the deep opening of the neck was edged with a garland of silver roses, and little silver roses outlined the edge of the narrow taffeta girdle.

A pretty collar of organdie was of the flaring stand-up shape, attached to a plain vestee of the same material. Both collar and vestee were edged with a hemstitched band of maize-colored linen, and the vestee was fastened with two maize-colored frogs. A little black moire tie was worn with it. Such a collar and vestee gives a smart look to a simple linen dress, and can be adapted in any color combination desired.

Victoria cases are little leather-covered boxes, of varying dimensions, usually four to six inches. The original forms opened with a fall-down top like a square kit bag; others open like a miniature suitcase. The little case is fitted with purse, scent bottle, mirror, powder box, comb, etc., leaving a little space in the center for a handkerchief. There is a strap handle at the top for carrying. These little cases are carried in place of a handbag, and are very smart. The first came over from England, but they are now made here, and cost from about $2 at a department store to any price the purchaser may wish to pay. There is a great variety in color and style. They are often called "party cases" or "beauty boxes," but the importers call them victorias.

Wrist watches for men sound like effeminate luxury to unaccustomed ears, but in reality they are a useful convenience, being made for horsemen in the hunting field, who would find it difficult to get at a watch worn in the ordinary manner. Wrist watches mounted in leather, of the utility type, cost about $6, while those for women's wear in gold, silver and platinum setting go up to imposing prices. The leather-set watch with a wrist strap is made for women as well as men, and is especially convenient when traveling or shopping.

Some of the prettiest hatpins to wear with the all-white hats are rhinestones set in silver in a mounting of white enamel; they cost from 50 to 95 cents. The heads are small, like all present hatpins of good style.

Leatherette gloves are a new fabric make giving a very close imitation of doeskin, white outside, yellow inside. They are cut as carefully as doeskin, with pique outer seams, in a mousquetaire gauntlet shape, tightened at the wrist by a strap passing through a slide. They are very smart-looking, and are washed more easily than doeskin or chamois; they must be washed with cold water, and laid flat, not hung up to dry. They are heavy enough for Winter as well as Summer wear, and cost $1 and $1.50 a pair.

Outing garments for women are sold by dealers in sporting goods. Very practical and inexpensive suits are made of olive-colored khaki. A Norfolk coat of this style is $3; a plain skirt with two pockets, $3; divided skirt, with buttoned panel in front, suitable for riding, cycling or rough walking, $4; bloomers to match, $2; leggings, $1. The same models, slightly more expensive, are made in cravenetted waterproof; in this material the coat costs $5; plain skirt, $5; divided skirt, $6; bloomers, $3, and leggings, $1.50.

Children's Kewpie handkerchiefs are a quaint little fancy; they are of fine linen printed in colors with a fancy border and a Kewpie in the corner. A box of three costs 24 cents.

The Rural Patterns.

When ordering patterns give number and size of pattern desired. Price of each pattern 10 cents.

8093, misses' surplice blouse. Cut in sizes 16 and 18 years. Size 16 requires 2½ yards of 36-inch material ½ yard

27 inches wide for collar, chemisette and cuffs. 8263, misses' middy blouse. Cut in sizes 14, 16 and 18 years. Size 16 requires 2¾ yards of 36-inch material, with ⅝ yard 27 inches for trimming. 8183, ladies' one-piece peg-top skirt. Cut in sizes 22 to 32 waist. Size 28 requires 2⅝ yards of 36-inch material. 8095, child's dress. Cut in sizes 2, 4 and 6 years. Size 4 requires 2¼ yards of 36-inch material. 8186, child's dress. Cut in sizes 6 months, 1 and 2 years. Size 2 years requires 1¾ yards of 36-inch material.

7325, ladies' five-gored petticoat. Cut in sizes 22 to 32 waist measure. Size 28 requires 3¾ yards of 36-inch material. 8128, misses' corset cover. Cut in sizes 16 and 18 years. Size 16 requires 1 yard of 36-inch material with 2¼ yards of

beading and 3 yards of edging. 7944, ladies' one-piece nightgown. Cut in sizes 34 to 44 bust measure. Size 38 requires 3¾ yards of 36-inch material. 7872, ladies' gathered blouse with square yoke. Cut in sizes 34 to 42 bust measure. Size 38 requires 2½ yards of 36-inch material with ⅜ yard 27 inches for collar and cuffs. 7588, ladies' shirt waist or blouse. Cut in sizes 34 to 40 bust measure. Size 36 requires 2¼ yards of 36-inch material with ⅝ yard 27 inches for collar and cuffs.

Vermont Olives.

Some time ago you gave a recipe for preparing green tomatoes so that they resembled olives. Will you repeat this?

H. M.

Take a bushel of green and half ripe tomatoes, wash clean, then pack in big jar or tub, using five pounds fine salt and one-half pound whole mixed spices. Weight down and cover with clear cold water. In two weeks they are fit to use, and will keep a year if kept under the pickle. They are used without further fixing, and you will find them a fine flavor of olives, but rather better and immensely cheaper, costing less than five cents a quart. The little plum or fig tomatoes are a nice size for using in this way.

Buttermilk Food.

This is a sure and simple remedy for indigestion and dyspepsia. If you have any trouble with your stomach you would better try it. Put yourself on a strict diet of this food and stick to it, and you will be cured. It is also good for babies, especially "bottle babies" with whom cow's milk and the prepared foods do not seem to agree. Let this food take the place of all others and they will soon laugh and grow fat.

Buttermilk Food.—Five cups fresh buttermilk; 3½ tablespoonfuls cane sugar; 2½ tablespoonfuls flour, browned. Mix the flour with a little of the milk as for gravy, mix all together, place on the stove and stir constantly until it has boiled three minutes. Keep in a glass jar in a cool place.

Barley Water.—Three even dessertspoonfuls of barley flour, a pinch of salt. Dissolve in a little water as for starch, then add five cups of boiling water. Keep in a glass jar in a cool place. Pearl barley boiled three hours and strained may be used in place of the barley flour. When ready to use mix the two ingredients, amount depending upon age. To start with use more barley water than buttermilk, but gradually decrease amount of barley water and increase buttermilk. "Grown-ups" should take it quite hot with a teaspoon, do not drink it.

E. M. S.

A Few Good Sandwiches.

SAUSAGE Surprise.—Fry some nice pork sausage to a delicate brown; drain, chop fine, then mix with enough smooth tart apple sauce to make a paste. Season with salt and pepper, and spread between thin buttered bread.

Cream Cheese and Liver.—Boil three chicken livers, then chop very fine with a small onion, one small pickle, three olives and a little green pepper. Add an equal bulk of cream cheese, season with celery salt and make into sandwiches with thin slices of rye bread.

Salad Sandwich.—Chop very fine two cucumbers, six green onions, six radishes and one mint leaf. Let it stand (marinate) in French dressing one hour. Drain carefully, then spread on white bread, add mayonnaise and make into neat sandwiches.

Salmon Sandwiches.—Drain canned salmon, flake carefully, removing skin and bone, then add tartar sauce to make a spreading paste, and make up with white bread. Tartar sauce is made like ordinary mayonnaise, but after stirring is finished one tablespoonful onion juice, one tablespoonful chopped capers and the same of chopped cucumber pickles are added to a two-egg mixing of mayonnaise. Chopped nasturtium pods may be used in place of the capers. This sauce is excellent with fish, or with cold jellied meat.

Cheese and Apple.—Mix half a cream cheese with one-third cup of tart apple sauce. Add chopped nuts if desired, and make into sandwiches with white bread.

Cheese and Horseradish.—Mix half a cup of grated cheese with half a cup of stiff apple sauce, and a tablespoonful of grated horseradish. Moisten with cream, either sweet or sour, season with salt and make up with graham bread.

Cheese and Pineapple.—Mix equal quantities of shredded pineapple and cream cheese, season with salt, pepper and lemon juice, and make up with white bread.

The Country Church in Colorado.

TWO miles from us is a small church, made of cement blocks. It has a small vestibule as entrance, an alcove for pulpit and organ. The windows are small, six lights to a sash, with green shades, common wood bottom chairs for seats. The floor is uncarpeted, but always looks clean. The platform where the choir and minister stand is carpeted. When the church was first built it was union, all denominations contributing to its cost, but after a short time it was thought best to put a vote for some one denomination. The meeting called out considerable feeling, but as the Methodists had the largest number of votes it was decided that way. Several families attend the church who did not join. As a church it has a small membership, but all seem to work together for a social center. The Women's Mission and Aid Society has started a meeting together of the people once in three months, at some one's house; take their dinners and have a real social time. The first was held last month at the house of the pastor, who lives on a homestead six miles from the church. They have but three rooms in their house, but one quite large, containing two beds, which were taken down, made room for the long table for dinner. At this meeting a very pretty silk and worsted crazy quilt was presented the pastor and wife from the church aid society with name of each donor worked on the blocks. It proved not only a great surprise, but a very happy one for the pastor and wife. The day was spent in friendly social enjoyment. It is the getting together, and mingling with others that gives one a feeling of interest and friendliness in others, also helps to break the monotony of life. We are all different; many are not congenial and not "our kind of people," but they are human.

In this Great Plains country one meets all sorts and conditions of life, although there is less of the foreign element than in some States. There are some young girls who take an active part in choir, church and Sunday school who are not only very nice looking and appearing, but modest as well; I am greatly charmed with them. One of the girls who is preparing for teaching, and very bright in her studies, asked me to come and see them in this manner: "Mrs. Johnson, we would love to have you come and see us, but we live in an old sod house, and it's a terror." I felt sorry for the poor girl; her father is one of the leading members in the church, a good man, I am told, but does not "get on in the world" financially very fast; has a large family of children and is trying to educate them so they can be of use in the world, a laudable ambition. We have some good singers, and a cabinet organ of very good tone. The young girl who plays just graduated from our county high school.

Very few have any flowers or shrubbery here on the plains, but a week ago Sunday a delightful surprise awaited us. On entering the church we saw large pitchers of lilacs on the platform steps. How beautiful they were, and brought to mind the great bush of lilacs by the window of my mother's room at the "old home on the hill" in New York State. There is no flower so "homey" as the lilac to me. It is like the robin among birds. We never had seen a robin since we came to Colorado until a few weeks ago, when I saw a big redbreast walking from the windmill towards the house. I almost held my breath, and tears came to my eyes at the sight of the "old home" bird. He flew away, did not sing one note, and I have never seen one since. In Wyoming there were lots of robins, but there were large trees and many of them.

The children are practising at Sunday school for "Children's Day;" that day usually draws a crowd. People who never attend church at any other time will go then. It is something out of the ordinary and attracts. They decorate the church as well as possible with what material can be had, mottoes and such like; all try to make the best of everything. The pastor is not an eloquent man by any means, but he preaches good helpful sermons. I never attended a Methodist communion until a short time ago, and I saw a great contrast in the little plain stand, with common ware pitcher and glasses with water colored with grape juice for the wine, from what I had been accustomed to in Nebraska, Kansas and the East. But it all meant the same. The presiding elder failing to come as expected the pastor served the bread and wine to the communicants who went to the altar. After service there is a general hand-shake and friendly intercourse which lasts some time. The people turn out well and 57 at Sunday school seemed a good number where the people are so scattered, and some so far away. There are whole sections where there is not a house. One cannot realize the conditions until she lives here and sees for herself. This Great Plains country has been settled twice before and abandoned by most. This third settlement is not nearly so thick as even the first, we are told. The superintendent of the Sunday school lives seven miles from the church, and some bring their children 10 or more miles. But riding over these prairies is very different from the rough, rocky roads of parts of Wyoming and Colorado I have seen. The little country church has a good mission to perform, and is a blessing in many ways to the people.

MRS. FREDERICK C. JOHNSON.

Sweet Cucumber Pickles.

WILL you give a recipe for making sweet cucumber pickles, such as we buy at grocery stores? I. B. W.

Soak four quarts of small green cucumbers in a strong brine for three days, then drain and cover with fresh water with one tablespoon of alum added, and let soak three days longer, then drain; wipe dry, and cover with weak vinegar; let them simmer in this two hours, then turn into the colander and drain. Make a spice-bag by tying in a piece of muslin one ounce each of cinnamon buds and allspice berries, and one-half ounce of celery seed. Put this in three quarts of vinegar, with one pint of brown sugar, and let heat until boiling hot; pour over the cucumbers, cover, and let stand until the next day, and repeat this for two mornings; the third day cook the liquor until syrupy, add the cucumbers and heat slowly until scalding hot, then pack in glass jars, pour the hot liquor over them and seal.

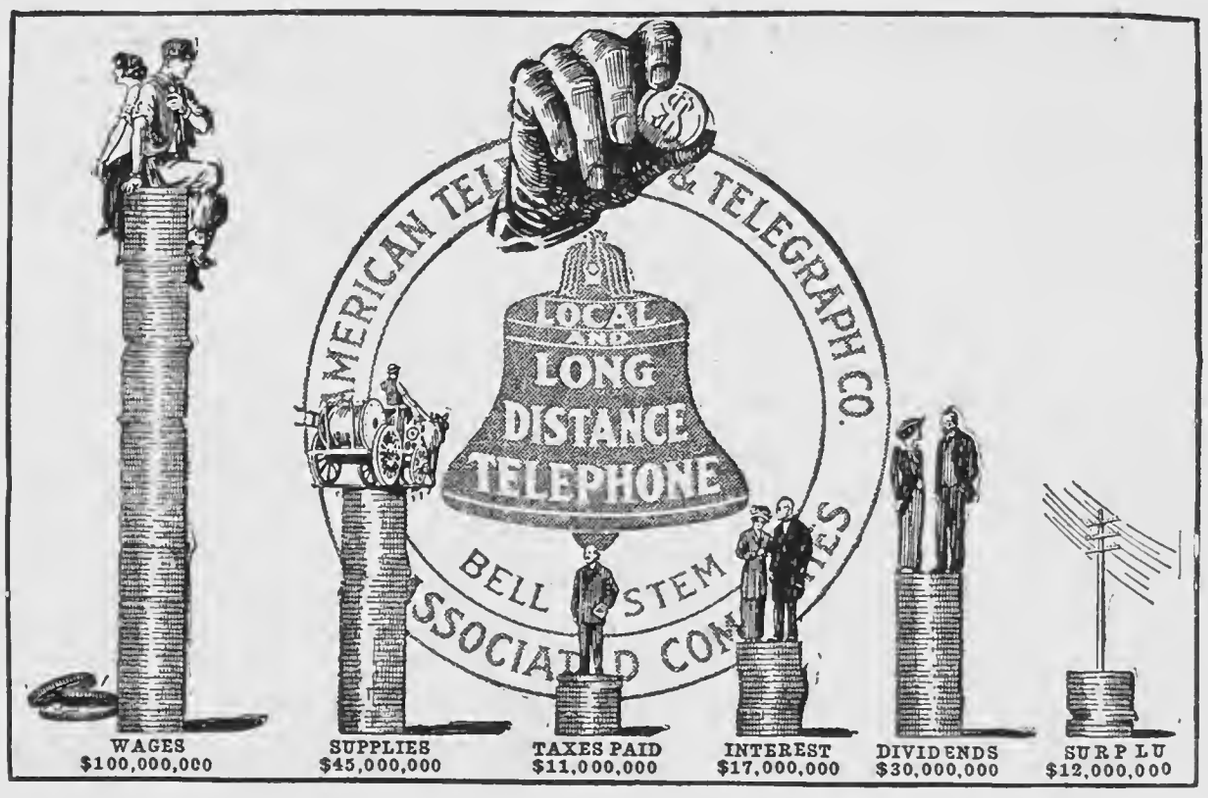
BOILING GREEN CORN.—The very best way to boil green corn, and I have tried a good many, is to put it into cold water to cover nicely, add one tablespoonful of salt for every half dozen ears, let it come to a boil, and boil five minutes. You will find it done and very palatable when cooked this way. I. M. B.

PEANUT BRITTLE.—Stir two cups of granulated sugar in a frying-pan over a hot fire until the sugar is changed to caramel. Pour at once over a cup of shelled peanuts, heated and turned into a shallow, buttered pan. When cold tap the pan, turn upside down, upon the table, to remove candy, then break into small pieces. The peanuts are at their best when fresh roasted. A. C.

The question of a night light for the sick room in a country home may be solved by borrowing one of the barn lanterns. Hang the lighted lantern outside the window; with the shade raised there will be plenty of light inside the room for most purposes, while the mere dropping of the shade will shut it out. There will be no unpleasant fumes inside the room, nor any absorption of the oxygen.
Michigan. M. E. S. H.

SWISS CHARD.—In your issue of March 21 you give a recipe for cooking Swiss chard. You say "the first young leaves are boiled," also "as the chard grows larger the leaf is stripped and only the mid-rib is used." I have grown Swiss chard for a number of years, the past two years the variety named Lucullus. This grows very large. We cut out the mid-rib and use the green leaves all Summer up to heavy frosts in the late Fall. Cook the same as spinach except that the large leaves may need cooking a little longer. F. A. C.

No great thing is created suddenly, any more than a bunch of grapes or a fig. If you tell me that you desire a fig, I answer you that there must be time. Let it first blossom, then bear fruit, then ripen.—Epictetus, about 60 A. D.



How the Bell System Spends its Money

Every subscriber's telephone represents an actual investment averaging $153, and the gross average revenue is $41.75. The total revenue is distributed as follows:

Employes—$100,000,000

Nearly half the total—$100,000,000—paid in wages to more than one hundred thousand employes engaged in giving to the public the best and the cheapest telephone service in the world.

For Supplies—$45,000,000

Paid to merchants, supply dealers and others for materials and apparatus, and for rent, light, heat, traveling, etc.

Tax Collector—$11,000,000

Taxes of more than $11,000,000 are paid to the Federal, state and local authorities. The people derive the benefit in better highways, schools and the like.

Bondholders—$17,000,000

Paid in interest to thousands or men and women, savings banks, insurance companies and other institutions owning bonds and notes.

Stockholders—$30,000,000

70,000 stockholders, about half of whom are women, receive $30,000,000.

(These payments to stockholders and bondholders who have put their savings into the telephone business represent 6.05% on the investment.)

Surplus—$12,000,000

This is invested in telephone plant and equipment, to furnish and keep telephone service always up to the Bell standard.

Indian Bead Work

NOTHING is more fascinating or more in vogue at this time than **Indian Bead Work articles.** We have procured an outfit for making these articles, which will be sent, delivery charges prepaid, for

ONE NEW YEARLY SUBSCRIPTION
OR
THREE YEARLY RENEWAL SUBSCRIPTIONS
(One of these may be the renewal of your own subscription for one year.)

This outfit consists of a Patented Loom for making articles, an instruction and design book, a spool of cotton, twelve H. Milward Sons' needles, seven bottles of colored beads—dark blue, green, light blue, black, red, yellow and white—a complete outfit to start the work.

Every woman knows and appreciates the value of these home-made articles.

Your neighbor needs *The Rural New-Yorker.* If he is not a reader get his subscription. If he is a subscriber get his renewal.

THE RURAL NEW-YORKER, 333 W. 30th St., NEW YORK CITY

Live Stock and Dairy

LARGER JERSEY CATTLE WANTED.

THERE is a tendency to breed Jersey cattle larger in the past few years. The average farmer has the impression that the "watch charm" size Jersey is typical of the breed, but this is not the practice nowadays. One Jersey man, Milo Fuller, of Ohio, declares that a good-sized Jersey cow should weigh 1,000 pounds, and there are many Jerseys which pass this mark. "Jersey breeders," he says, "are now considering the 900-pound cow small, and bulls frequently weigh from 1,700 pounds upward to a ton. Stoke Pogis III weighed 1,800 pounds, and one of the famous bulls of the breed approached the 2,100-pound mark. The reason for there having been so many small Jerseys scattered about the country is that the breeder chose a cow for a dooryard pet, rather than for capacity, and the billionaire farmer for years fancied the small cow. This fatal mistake in breeding small Jerseys was at its highest in the eighties. In the nineties the idea of breeding them larger took hold of those higher up in the Jersey business. The small Jerseys still persist on the average farm. The St. Lambert family are large cattle, the Island bred cattle are smaller than the American and English-bred cattle. Yet there has also been a tendency in the Islands to breed the cattle larger during the past five years.

"The farmer who has small cattle should improve them by breeding to a purebred registered bull. The weaker the stock, the better the sire should be. The average farmer with grade stock inclining toward the Jerseys should breed larger, and breed to better stock. Keep in sight the work of the prospective bull's dams. I would rather have an animal with a good mother, one that was tested and gave good results, than to go back three or four generations and find a half-dozen dams of high ability. There is a greater demand for high-testing milk. This demand is greater than in the old "cheese factory days," and the average farmer must either turn to high testing breeds, or if he has a low testing breed, look for bulls of high-testing families of that breed. All breeds are being perfected, and the demand for a good per cent. of butter fat, together with economical producing ability is what the farmer must secure.

"The points which the farmer should observe in selecting a Jersey, a Holstein, an Ayrshire, or any dairy cow are similar. We want the wedge shape, thickness through the hips, thin through the shoulders, thin thighs, well-balanced udder, long slim tail, a level back, a good intelligent head. I look for a good milk well, good-sized, and wandering milk vein. I look for intelligence in the animal. There are some animals that show intelligence in their countenances, and others have a stupid look. I believe stupidity is an evidence of incapacity in an animal as well as person. I like to see a bull formed like a cow, broad through the hips and narrow through the shoulder. I don't like surplus meat on an animal, for every extra pound throws that animal in the beef class. I look for rudimentary teats on the bull, the same as on a heifer. I like these rudimentaries wide between each other, as teats should be on a cow's udder. These principles seem to hold good in the dairy breeds, and the farmer should observe them."

O. Platt, of Ashtabula County, states he is not breeding his Jerseys under 22 months of age. This allows them to acquire size. He was unfortunate in having one freshen at 16 months, and her growth was seriously handicapped.

W. J.

SALTING THE COWS.

COW TESTING IN WISCONSIN.

THE State of Wisconsin is doing some remarkable work in organizing farmers into coöperative work. All sorts of things, from selecting seed potatoes to studying music, are organized and directed until Wisconsin is rapidly taking its place as the leading agricultural State in the Union. This is not due to the fact that Wisconsin has superior advantages of climate or soil, for other States in the same latitude have the same. Wisconsin's gain is due to the fact that farmers are organizing and concentrating their efforts along definite lines. As an illustration, take the following report of the record of 10 herds of cows in the Ellsworth Cow-testing Association. As we see, this is a high school test, the work in each herd being done by a boy in the agricultural course. Here they have found a robber cow which cost her owner over $5 per year, and another liberal worker which paid a profit of over $69. Very likely the robber was getting away with a reputation for paying a profit until the boy exposed her record. This chasing out the robber cows is what is to make Wisconsin the great dairy State rather than cheap bran or alfalfa soil.

Complete record of best cow, owned by F. C. Teubert, Beldenville, Wisconsin. Herd cow No. 79, grade Holstein.

Total milk.	Av. test.	Butterfat.	Value of butterfat.	Cost of feed.	Profit
Lbs. 8,276	4.2	370.84	119 85	*Dollars.* 50.85	*Dolls.* 69 48

Fourteen of 18-Short-horns were of beef type. During the testing year 11 cows were sold, one died, one sick. Two of the cows were old and hard milkers; two were kickers, two were hurt, and four were too small. One sucked herself.

Complete record of poorest cow, owned by W. M. Leonard, Ellsworth, Wisconsin. Herd Cow No. 78. Scrub.

Total milk	Av. test	Butterfat.	Value of butterfat.	Cost of feed.	Loss.
Lbs. 1,375	4.4	60	*Dollars.* 18 83	*Dollars.* 24 04	*Dolls.* 5 21

Out of the 87 cows in the 10 herds the following is their breed:

Scrub.	Grade Holstein.	Grade Shorthorn.	Red Polled.	Grade Jersey	Grade Guernsey.	Purebred Guernsey
44	11	18	1	6	1	6

This record was of the first 10 herds in the Ellsworth High School C. T. A. that finished the year's work. After all the records were in, the best cow shown here was beaten by a grade Holstein which gave nearly 400 pounds butter fat. There were nearly 25 herds in all, each one tested by a boy in the agricultural course.

RALPH LOCK.

AILING ANIMALS.

Chorea.

I HAVE a young sow about six months old that has apparently lost use of knee-joints in hind legs. It can walk fairly well without bending its knee-joints. When standing at the trough to eat slop its hind feet keep moving up to its body, first one and then the other alternately. It eats well and seems to be well otherwise although it is getting thin. I think it was caused by running along the wire fence biting at some little pigs outside. It has been in this condition now for several weeks without any apparent changes. What can be done for it? E. H.

Maryland.

We suspect that the pig has chorea (St. Vitus dance) which is incurable. She should not be used for breeding. Let her live an outdoor life so far as possible and feed mixed rations including 10 per cent. of digester tankage. A. S. A.

Catarrh.

MY horse has chronic catarrh, has had it for three months. He is in fair shape, weighs about 1,350, his weight when well is 1,500. Discharge is from one nostril and smells offensive; his teeth in good shape. I have had two veterinarians for him; they did him no good. He has no cough. W. F.

Maryland.

A diseased molar tooth is commonly the cause of a bad smelling discharge from one nostril, or there may be a collection of pus in a sinus, or the horse may have glanders. A graduate veterinarian should examine the horse and if he finds glanders absent the tooth should be removed by trephining or the sinus opened by trephining for removal of pus. Home treatment will not avail in such a case. A. S. A.

Depraved Appetite.

I HAVE a cow f ur years old; she is hardy, a good milker, and butter-maker, but she has a craving for bones, leather, meat, etc. She got in horse stable, ate up a set of lines and some other harness, swallowing buckles and all. She stays quite thin, has a good appetite, but will leave everything for a piece of leather or a bone. Can you tell me the cause and if anything will stop it? A. A. H.

New Jersey.

If you are sure by the tuberculin test that the cow is free from tuberculosis feed her bran freely at each meal and if this does not suffice mix a tablespoonful of precipitate phosphate of lime in her feed twice daily, or allow an equal amount of bone meal. Powdered charcoal may also be freely used and the cow should have access to rock salt. Feed a mixed ration. A. S. A.

Contracted Hoof.

MY horse is sore in one of his front feet; is not exactly lame, but he favors it a good deal, and after driving he acts as if it was sore. The frog is very hard and brittle and at the back part of the hoof it looks cracked. What can I do for it? J. F. N.

New York.

Poultice the foot for a week with hot flaxseed meal to which add a little bran to prevent sticking. Wash the hoof clean on discontinuing the poultices and then apply lanolin freely once a day. Keep the horse off board floor and have him worked or exercised every day. A. S. A.

When you write advertisers mention The R. N.-Y. and you'll get a quick reply and a "square deal." See guarantee editorial page.

PORTER

PERFECT BARN EQUIPMENT

A Clean Barn
Cow Comfort
More Milk
Added Profits
Less Labor

are results where Porter fixtures are used. Any cow, to do her best, must have the comfort, cleanliness and contentment such as Porter Dairy Barn Equipment affords. It will actually pay for itself in a year in added profits. Modernize your barn, make more money and save work by installing fixtures bearing the name that stands for recognized leadership, "Porter." Let our barn experts help you. Send us sketch showing size and arrangement of your building and we will send floor plans complete, free.

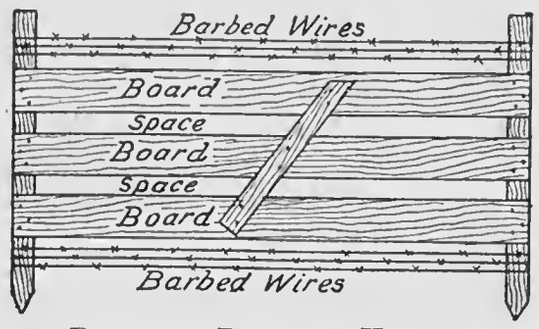
PORTABLE HOGPEN.

REFERRING to inquiry of L. D. M., on page 872, following is brief description of a simple, inexpensive and serviceable portable hogpen, which I made, and find entirely satisfactory for a few pigs or hogs, a calf, etc. With the materials on hand, it can be made by one person in half an hour or less.

For the corners use four 4x4s or 2x4s, three to five feet high as desired. To these posts nail, for each side, two or three one-inch boards, six inches wide, making a pen eight, 10, 12 or 14 feet square, as desired. Nail the bottom



PANEL OF PORTABLE HOGPEN.

boards three or four inches above the bottom of the posts, so that the board will not touch the ground where uneven, and cause the pen to tilt or teeter. Below the bottom board and above the top board stretch and nail two or three strands of barbed wire to discourage attempts to root under or climb over. To steady the sides, nail them together in the center with a cross piece. Leave a space of about two inches between the boards; this allows better circulation of air and is pleasanter for the pigs than being cooped up day after day within a tight fence through which they cannot see. For ease in transferring from one pen to another, etc., one corner may be fastened with hooks instead of nails; there will be enough "give" in the other three corners to allow for opening wide enough for hogs to pass through.

There are many advantages in such a pen for a few animals in Summer. It is so light that it may be readily carried or moved about by one man or a couple of boys, without removing the hogs. By shifting the pen every few days the ground does not become foul, the animals keep clean, and the manure may be left where wanted without handling. The pen may be set under a tree or any place where the ground needs loosening up, and the hogs will do a thorough job, and incidentally destroy every white grub within reach. C. B. LOOMIS.

Exhibiting Bull.

I HAVE a very fine Guernsey bull, 15 months old, and wish to exhibit him at the county fair. He is very gentle. Do you think the noise and publicity there would tend to make him start to be ugly and ill-tempered? Besides my bull, which is kept in a pasture by himself, I have a two-months-old purebred bull calf, just weaned, that I am keeping in a box stall. Could he go out to pasture with the 15-months-old bull, or would the latter injure him? I suppose it would be unwise to let him run with the cows. All the Guernseys I have ever heard of or seen pictured have horns. Would it detract from their value to be dehorned, or are even the bulls considered so tractable as not to need it? G. G. H.

The bull will not be likely to lose his gentle disposition if some of his regular human friends go along with him. If left to the care of strangers he might be teased or angered by careless treatment. A bull knows his friends and is usually safe with them. We would keep the young bull by himself in a small pasture, or tied on good grass with a long rope or chain. Do not let such a calf run with the cows. Except for exhibition purposes in the show ring the cows are better with their horns taken off. The judges will allow a few extra points for well-shaped horns, but safety is better than "points." L. M.

Relining Silo.

I HAVE a square silo which will have to be relined. Shall I have to take off all the old lining or would it do to leave it on? Which would you advise, a lining of wood or lath and cement?
Fabius, N. Y. J. R.

Unless the lining of the silo is so badly decayed that it will not hold nails, I would not remove it, as I am "guessing" that it is a single thickness of boards, but re-cover it, and so add to the strength of the walls. Now that lumber good enough to face a silo with has become so high in price, it may be that it would be the better plan to lath and cement it, provided the frame is of sufficient strength to hold the walls from springing and cracking the cement. When such a plan is pursued, you can add to the value by coating over the cement with a coat of gas tar (not coal tar) and gasoline, cold mixed—which will make the wall both air and moisture proof. If you cement, you have the choice of stripping up the walls, and using common lath, or get the solid grooved board lath, or metal lath, about which you can best choose by pricing the cost of labor. The cement plan at this distance appeals to me. JOHN GOULD.
Ohio.

Color in Dairy Products.

NOW comes the Department of Agriculture claiming that the food has more to do with coloring both milk and cream than the breed.

"Chemical tests show that the yellow pigment in milk consists of several well-known pigments found in green plants. Of these the principal one is carotin, so called because it constitutes a large part of the coloring matter of carrots. The other yellow pigments in the milk are known as xanthophylls. These are found in a number of plants including grass but are especially abundant in yellow Autumn leaves.

"These pigments pass directly from the feed into the milk. This explains the well-known fact that fresh green grass and carrots increase the yellowness of butter, the only standard by which the average person judges its richness. On the other hand, a large proportion of these pigments is deposited in the body fat and elsewhere in the cow. When the ration is changed to one containing fewer carotin and xanthophyll constituents, this hoarded store is gradually drawn upon and in consequence the yellowness of the milk does not diminish so rapidly as it otherwise would. This yellowness increases, however, the instant the necessary plant pigments are restored to the ration.

"Green grass is probably richer in carotin than any other dairy feed. Cows fed on it will therefore produce the highest colored butter. Green corn, in which xanthophylls constitute the chief pigment, will also produce a highly colored product. On the other hand a ration of bleached clover hay and yellow corn is practically devoid of yellow pigments and the milk from cows fed upon it will gradually lose its color. It is, of course, indisputably true that the breed does influence the color of the milk fat; but vary the ration and there will be a corresponding variation in the color of the milk fat in each breed."

At the same time all who have fed cows of the different breeds know that Guernseys and Jerseys certainly make a darker-colored milk than other breeds. The Guernseys are particularly noted for this. The Department admits this in the following:

"In cows of the Jersey and Guernsey breeds the body fat is frequently of such a deep yellow color that some butchers and consumers look with disfavor upon beef from these breeds. For this prejudice there is absolutely no justification. The yellowness of the fat springs from the same causes as the yellowness of the milk fat and there is no reason for objecting in one case to the very thing that is prized in the other."

What is Dairy Cleanliness?

I WAS much interested in J. J. D.'s account of the Lincolndale school, farm and dairy. The point I most wish to touch upon is the three washings given the cow's udder. Is this scientifically the thing to do? We never wash an udder except when milking begins immediately, and never leave a cow until finished. Any work on the udder causes the milk to start, and the muscles expand painfully if not at once released.

My father liked milk direct from the cow and lived beyond his four-score years, and I also have hidden many gallons of the warm fluid that the strainer never inspected. I also am certain my father's cattle were subject to cow ailments much more than any I have ever owned, on account of improved care I think. We have always had an enviable reputation from our farm dairy products, and yet we feel almost filthy compared with those everlasting washings, groomings and snow white garments of the milkers we frequently read about. Will someone please tell us if we are "horribly unclean?" The old ways of decent cleanliness taught us by our good butter-maker mothers seems like barbarous relics of the past compared with some of these certified methods of today. J. E. H.
Emporia, Kans.

"DOESN'T it give you a terrible feeling when you run over a man?" they asked him. "Well, if he's a large man," replied the automobilist, "it does give one a pretty rough jolt."—Ladies' Home Journal.

DAIRY CATTLE

GUERNSEY BULL REGISTERED, ready for service, $75.00. Tuberculin tested, Reagan Bros., Tully, N. Y.

FOR SALE—Two Registered Guernsey Bull Calves imported dams. Sire—Golden Secret of Follyland. JOHN JACOBS, New Baltimore, New York

For Sale—A fine Guernsey Bull. Three years old. Own son of the great Masher's Seqnel. Bargain. Address Stuart R. Mann, Derby, N. Y.

GUERNSEYS FOR SALE
Two cows fresh this Fall; also a few heifer and bull calves, Sired by Prides May King of Linda Vista No. 18617, ont of dams of best blood.
FOX RUN FARM
F. S. GILCHRIST, Superintendent - Peterboro, N. H.

FOR SALE—Trio registered Ayrshires. Three months old. First class. John M. Lewis, Alfred Station, N. Y.

FOUR REGISTERED AYRSHIRE BULL CALVES, two, three, six and seven months old. Beautifully marked. Offered by WORONOAKE HEIGHTS, WORONOCO, MASS.

Holstein-Friesian Bull Calves For Sale—Write for special offer. THE GATES HOMESTEAD FARM, Chittenango, N. Y.

HOLSTEINS
100 cows due to freshen in Sept. and Oct.
100 fresh cows and springers.
PRICE, $75 to $100.00 EACH
All large, well bred, nicely marked and heavy milkers. 100 2-year-old heifers due to freshen this Fall, and all in calf by registered bulls. You can pay more but you can't buy better.
F. P. SAUNDERS & SON, Cortland, N. Y.
Office, 50 Clinton Ave.

Purebred Registered
HOLSTEIN CATTLE
Last year a California Holstein made a yearly record of 784.13 pounds of fat from 25,981.8 pounds of milk.
After an interval of two months she began another yearly test which has just come to a close with a record of 868.1 pounds of butter fat from 28,826.4 pounds of milk.
These two successive yearly tests during which 54,800 pounds of milk were made are more evidence that great records are not spasmodic efforts, but represent capacity permanently developed.

Day after Day, Year after Year,
PRODUCTION COUNTS
It is not what a cow can produce in 7, 14, or 30 days, even in a year that determines her value to the farmer. It is what she can do in a lifetime.
Brown Swiss Cows rank high in average production and are regular and persistent breeders and producers. Year in, year out, they make good records and raise good calves without any coaxing or pampering. If interested, we will send you an illustrated booklet.
The Brown Swiss Cattle Association
IRA INMAN, Secretary BELOIT, WISCONSIN

SUMMER FEEDING OF DAIRY CATTLE.

THE favorable influence of early Spring pasture on the milk flow is very well known. As a rule, the cows will obtain enough food from pasture alone during the early part of pasture season to make large secretion of milk, but later in the season it is absolutely necessary to supplement the pasture, which can be done by feeding grain, silage, or crops that are green.

The flies are blamed for the marked falling off in milk during hot months of July and August. It is true that flies do worry the stock, but if the animals were given some succulent roughage, as green crops or silage, they would not have to graze for a long time over a large area on dry pasture in the hot sun to be pestered by the flies. A good spray of fly oil before going to pasture will save feed. Some dairymen stable their cows during hottest part of day, feeding them inside then with green forage crops.

Most cows will give more milk on grain in addition to pasture, but usually not enough to pay extra cost of grain and feeding it. Grain is only profitably fed to heavy milkers, which will make them produce a maximum amount of milk. Therefore, really the only methods of feeding are soiling or giving silage. Soiling consists of cutting crops and feeding them fresh and green. Soiling crops are succulent, palatable, easily digested, and stimulate a flow of milk. They are fed in large quantities, 60 pounds being fair allowance; grain only being fed to heavy milkers, in addition to pasture. While crops to be used may be varied, a good example is the rotation employed on the writer's farm. Oats and peas sown in April, cut and fed from middle of June to middle July. From middle July to August first green Alfalfa is fed to cows. From August to October green fodder corn is fed which is planted in succession in Spring. A change is made now and then from corn to Soy beans or cowpeas, or any crop as we happen to have.

While soiling has many advantages, the biggest drawback is the increased labor, such as seeding, cutting and hauling this heavy green food. The feeding of silage cuts out a great deal of this increased labor and at same time provides a succulent feed, stimulating a large milk flow. Therefore a good dairyman should have an extra silo filled with corn for Summer feeding, or have one large enough so he can supply his cows with succulence during Summer. The feeding of silage is the most economical method of supplying food for stock during hot, dry periods of Summer when pasture is short.

New Jersey. J. W. G.

THE HOG A DAIRY PARTNER.

"MANY of us dairy farmers are losing good cold cash by neglecting to keep a few hogs," says Edward Williams of Ohio. "I keep but a few cows, and am an average representative of the small dairy farmer of Eastern Ohio and of other States. I have learned the value of a good bunch of porkers, and I have $350 or $400 each year to my credit from hogs which supplement my small dairy.

"My milk brings only cheese factory prices. I have whey left. My neighbors are keeping but two or three hogs for family use. They are making poor use of the whey product which I am turning into hogs. I am not a scientific feeder; I do not practice pasturing or hogging down corn as is done in the corn sections. I have a hog pasture like other small farmers; I buy feed as they do, and I have my book here to show they have paid me and will pay other dairymen as well as myself. In fact a number of my neighbors would be pleased with a $400 annual income from a half a dozen scrub cows, while it comes my way easy from the hogs I sell annually.

"I sell 20 to 30 hogs each year. I aim to have them weigh about 175 or 200 pounds at five and one-half or six months of age. The hogs return me about $15 the head, sold to the local buyer. I do not keep careful account of interest on investment, or possible loss from disease, but what I have done is this: I have sold myself May 3, five pigs for $20. That is a pretty good figure. On September 7 I marketed four of the five pigs for $59.92, and have one left, which I value at $15. I purchased the feed stuff, paying $23.92 for hominy and shorts. After all I am about $51 ahead on this bunch at a total expense of about $24 for feed. A farm accountant might show me in dollars and cents that after computing labor I might be losing money, but a $51 margin is pretty good on this bunch. I do all my own work, and it pays me to keep a few hogs much better than a lot more scrub cows.

"Here is the point. There are farmers who have become disgusted with slow maturing hogs; they saw no profit in them, and quit. I know one instance where a tenant declared he had fed 14 acres of corn to seven hogs. They were two years old when butchered, and at every stage of the game they were a losing proposition. This is the way the average farmer has played with hogs, and it hasn't paid. It isn't paying me as well as should I sow rape for Autumn pasture, have some rye for Spring and Fall pasture and supplement my ration with tankage. I do feed green sweet corn on the stalk. There is but little difference in breeds. I have the O. I. C. and I find they mature quickly. Hogs nowadays mature more quickly than a score of years ago, yet there is too much of that old blood still kept on the average Eastern farm. Many farmers draw on their income from the farm to pay for the meat supply. Keep a few hogs, and they will increase the income materially. Keep two or three sows, have them farrow in March or April and in August or September, and they will pay."

W. J.

DO OLD HENS PAY?

CAN you print any figures showing the comparative egg yield of hens in their second year? Prof. James Dryden conducted some experiments along this line. Can you get his figures and tell us whether it pays to keep old hens for laying stock. E. J. S.

The Utah experiments which were made by the writer, and were conducted for a number of years, showed average pen results from Leghorns in the first year of 164 eggs, and in the second 126 eggs per hen. Of course, this refers to averages and it is not possible to give any figure that will represent the laying of all flocks, as you know they vary so much, even in the same breed. In exceptional individual cases, more eggs were laid in the second year than in the first. For instance, a hen laid 201 eggs the first year and 241 the second. Instances such as this might be given for a number of flocks. Forty-one hens of different breeds with individual records averaged 171 eggs the first year and 125 the second, or 40 per cent. more the first than the second.

At the Oregon Station later results were secured as follows: A flock of 50 Barred Plymouth Rocks laid 160 eggs the first year, and 105 eggs the second year. Fifty White Leghorns and crosses laid 151 eggs the first year and 130 eggs the second year. In these experiments the laying year began November first. Out of the 100 hens 17 laid more eggs the second year than the first.

The conditions as to time of hatching and kind of care and feeding have a good deal to do with the number of eggs laid the first and second years. Where the conditions are more favorable during the second year than the first a better egg yield will be secured in the second year. Again, where the period of maturity varied or where the laying year began in the Spring, the second year records were greater than the first, but where maturity is reached in the Fall and laying begins, then, the average flock results invariably showed that the first year is the most productive, and that there is a gradual decrease each succeeding year. When the first experiments were made at Utah the prices of eggs were very much lower than now. On the showing then made it looked on the face of it that it would be possible to renew the flock each year where eggs were produced for market purposes. Since then the prices have risen to a point where it seems that it will pay to keep the flock two years. While the production is very much greater the first year, the eggs weigh more the second year, and if one has a select trade this will figure some in the calculation.

Again, the cost of raising the pullet is considerable, in fact the business of hatching and raising the stock is probably the most troublesome part of the poultry industry. If a good pullet could always be raised at a cost not exceeding the price received for the old hen, then it might pay to renew the flock every year. But I think it is very doubtful, with present methods of hatching and rearing the chicks, whether this can be done. It is not a question merely of raising the pullet. It is a question of rearing one that will have equal vigor and laying qualities with the parent. The great danger in the frequent renewal of the flock is that through faulty methods of hatching and rearing the vitality of the old may not be preserved in the new flock. If the poultryman is very successful in the hatching and rearing of the chicks he will, I think, find profit in renewing the flock each year, taking the flocks as we find them as a whole. I hope some time that the productive period of the hen may be lengthened. I have had enough individual cases where the second and even third year's production was higher than the average of the first year, indicating that it is possible by proper breeding to lengthen the period of profitably laying. If this is done it will be a great boon to the poultry industry.

JAMES DRYDEN.

Uneven Span Henhouse Roof.

WOULD there be any disadvantage in a poultry house made with a gable, one side of the roof being shorter than the other, the side toward the south? If this short side of the roof were made partly of glass, or even entirely, I can see some important advantages, but don't care to build a house that way if experienced poultrymen have good reason for never doing it?

New York. F. W. B.

The points to be taken into consideration in building a poultry-house roof are economy, durability, and convenience, and the type of roof which will best serve these ends will vary with the size and proportions of the house. For a house which does not exceed 16 feet in width the single slope, or shed roof is usually preferred; it is easily built, throws all rain water to the rear, gives a high front for windows and sufficient head room. It is difficult to span a greater depth than 16 feet with single rafters and consequently a deeper house is best built with a gable roof, either the ordinary type with rafters of equal length or one having the rafters of one side shorter than those of the other, the latter being called a combination roof. With the same pitch of roof and area of ground covered, a shed roof, gable roof and combination roof require the same amount of material, but the combination roof requires less height of rear wall than the gable roof and less height in the front wall than the shed roof; it is, therefore, a favorite type in poultry-house construction. A half monitor roof is one in which the short front rafters do not meet the long rear rafters but are dropped some distance below them. This gives a saw tooth effect much used in modern factories, the vertical space between the ends of the two sets of rafters being provided with windows for light and ventilation. This is an excellent type for very deep buildings as it admits sunlight to the rear of the building. Monitor roofs, hip roofs and A-roofs are also used to advantage on buildings of special construction.

THE EGG-LAYING CONTEST.

THE thirty-seventh week—ending July 17—shows an egg output of 3,102; 26 eggs more than were laid during the previous week. The top-notcher this week is pen number 42, score 58; the "sour milk" pen of White Leghorns from Storrs Agricultural Station. This pen has laid a total of 1,539 eggs, which is only five eggs less than Tom Barron's White Wyandottes. One week more and they will pass the Barron birds and take first place in the record; but as they are entered as an "experimental" pen, and do not contest for the prizes, Barron's real contestant is the pen of Francis F. Lincoln's White Leghorns from Mt. Carmel, Conn. This pen laid 51 eggs this week, and has a total of 1,517; only 27 eggs behind the Barron White Wyandottes. Chas. Heigl's White Leghorns from Ohio are second in the week's score with a record of 57; two Pennsylvania pens tie for third place with scores of 56 each; they are Marwood Poultry Farm, Butler, Pa., and P. G. Platt's pen from Wallingford, Pa. Tom Barron's Leghorns are fourth with 54 to their credit. Pen number 40, from Storrs Agricultural Station, laid 53, and Geo. A. Cosgrove's pen laid 52, N. W. Hendryx's pen laid 50, Thos. W. Moore's pen 50, and C. H. Savage's pen 50. In all 12 pens of White Leghorns laid 50 or over, and not a pen of any other breed reached that number, though H. P. Deming's S. C. Reds came within one of it, laying 49. Below is the week's record:

GEO. A. COSGROVE.

Tame Leghorns.

MOST people regard the White Leghorn as a high-strung, nervous fowl, flying out of her skin at the least disturbance and, as many people express it, "wilder than a hawk." Let such people consider the picture shown at Fig. 415, page 967. Here are White Leghorns about as tame as a hen can be. They are literally eating out of the hand, and no one could ask more friendly birds than this little group, and yet when these birds were entered in the egg-laying contest, they were wild as partridges. The night before they were sent to the contest they were picked out of a tree, had never been housed or petted, but had run free all their lives. When they came to the Storrs egg-laying contest, Prof. Kirkpatrick and his attendants became interested in them, and made an effort to tame these wild birds and make friends with them. We see the result in the picture. This pen of Leghorns was entered by C. H. Savage of Connecticut. They have made a fair record; up to July 17 the 10 birds laid 1,114 eggs, producing 50 during the last week. We print the picture to show what can be done with kindly treatment and thorough care. It certainly is far better to have Leghorns that will eat out of your hand rather than wild birds which are ready to throw a fit the moment you make a quick movement with one of your hands.

Brown or White Eggs.

Is there any difference except in external appearance between brown-shelled eggs and white ones? Do they differ chemically or in nutritive value, and if so how? F. S. D.

There is practically no difference in analysis between a brown-shelled Light Brahma egg and a white-shelled Leghorn. The feed may make some difference in color of egg, but an egg seems to be an egg.

Weight of Broilers.

CAN you tell me what broilers should weigh and about how much they will dress away? H. M.
New York.

Broilers should weigh from one and a half to two pounds, live weight, though early in the season somewhat lighter ones will be accepted at market rates. Many are sold at a pound and a quarter. I do not know what weight broilers lose in dressing but it could be easily ascertained by weighing one before and after dressing it. M. B. D.

An Egg Buyer Talks.

I HAVE had some experience in buying eggs, and so am interested in this egg controversy. I sent away for choice eggs and only three out of 15 hatched. I did not "set them in the ice box or oven," as one seller seems to think we do. I bought "purebred White Wyandotte" eggs and have three black chicks from the hatch. Is it because I did not set them right?

We who buy send cash for eggs, and just common sense would indicate that we are as anxious to get results as the seller. He has his money and we have nothing if the eggs don't hatch. Each seller sends different directions or none as to setting the eggs. I haven't a doubt that every buyer does his best to get a good hatch. What would we bother with them for, otherwise? Some of the eggs that I bought were broken when they arrived. Buyer's fault, of course.

There are two sides to this question, and there are just as many honest buyers as sellers. All buyers are not fools any more than all sellers are sharpers. It will not improve the egg trade for the sellers to sneer at and doubt the honesty of their patrons or question the existence of brains among them. They may settle down to raising just common barnyard fowls. FLORENCE HOAG.
New York.

BOSTON MARKET REVIEW.

THE supply of fruit and green stuff is plenty and prices of course rule low accordingly in most cases. This is the consumer's opportunity and is duly appreciated in most cases. The grower has had the inside track and is willing the other fellow should have an inning at this time, as a large crop which returns only a low price comparatively, however, if in demand, so as to be moved quickly when brought to market is many times a paying crop at that. String beans, cabbage and cucumbers are too plenty and in over supply, they demand 50 to 75 cents per box on the beans, 50 to 75 cents per barrel on the cabbage, and $1 to $2 per box on the cucumbers are about the prices. Most other stuff cleans up fairly well and tomatoes and squash are short. Native tomatoes bring $3.50 per box, hot-house, 12½c. per pound; Southern stock about $1 per crate. Summer squash, 75c. per dozen; Summer marrow, $3 per crate. Yellow turnips, $2 per barrel; white turnips, 50c. per dozen bunches; beets, 30c. per dozen; carrots, 60c. per dozen; radish, 50 to 75c. per box in bunches. Rhubarb, 65c. per box of about 40 pounds. Peas, $2.50 per box; sweet corn, 30c. per dozen. Cauliflower, $2 per dozen. Celery, $1.50 per dozen; spinach, 50c. per box; lettuce, 35c. per box. Onions are working down in price as the supply increases and native sets are being cut; these bring about $2 per bushel. Potatoes have been out of season in price, but are more plenty and working lower; $2.50 to $3 is the price now per barrel, with sweets going at $4 per crate.

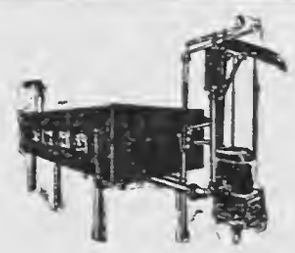
A few Southern apples bring $1.75 per basket, others $1, which is also the price for the few natives which appear. Yellow bananas, $1 to $3 per bunch, with reds going at $2 to $4.50. Blackberries, 14c. per box; blueberries, 15c.; gooseberries, 6 to 10c.; raspberries, 10c. per pint; strawberries, 15 and 18c. per box; currants, 5 and 10c. Canteloupes or muskmelons are not too plenty and bring $1.75 to $4 per crate. Sour preserving cherries, 6c. per pound; sweet cherries, 10 to 15c. per pound. Grapefruit, $3 and $4 per box; lemons, $5 per box; oranges, $2.50 to $5 per box. Pineapples, $3 to $5 per crate; peaches from California, $1 per box; from Georgia, $2 and $3 per carrier; plums, $1.50 per carrier; watermelons, 25c. and 30c. each.

Receipts of butter are not too heavy, especially of best grades, and prices rule up a little, yet some dealers say a decline is likely to follow as the recent rise will bring in heavier shipments from some points. Best tub creamery, 30c. and 31c. per pound, with boxes and prints, 1c. per pound higher; best Western creamery about 30c. is the price; good and fair creamery, 26c. and 28c. Cheese in good supply and demand not heavy yet prices rule about the same at 15, 16, 17 and 18c. per pound, according to grade.

Fresh eggs in demand, both in city and country centres, and supply not too plenty; price going slowly up. Young stock brings 34c.; good, fresh stock, 30 and 31c.; others from 24 to 28c.

Live and dressed poultry are in fair demand. Dressed fowls of best quality, 18, 19 and 20c.; medium, 16 and 17c.; broilers, 23 and 25c.; turkeys, 25 and 27c.; ducks, 16 and 17; live fowls at Brighton and Boston market, 16 and 17c.; broiler chickens, 19 and 20c. Beef cattle on hoof, $8.75 for best, per hundred; good, $6, $7 and $8; medium, $5 and $6; other poorer grades, $2.50 to $5 per hundred pounds. Dressed beef, 12 to 18c. for good and best; a few poor grades, $8 to $12. Hogs on hoof, 8½ to 9½; dressed, 11½; live veal calves, 9½ and 10½c. per pound.

Milch cows in fair supply and slow demand; common milch cows, $50 and $60 each; a few good ones brought about $90 each. Horses in demand and prices range from $325 to $425 for best heavy stock, $225 to $325 for medium, and $135 to $225 for light general purpose stock. A. E. P.



Capacities, 1,200 to 20,100 Eggs
(Sectional Construction)

The one money-making, labor-saving hatching machine is the Hall Mammoth Incubator—the original and standard. As a producer of poultry profits and satisfaction it has no equal.

The Hall practically costs you nothing. Wise users figure that it pays for itself by giving extra profits in larger hatches of the strongest, liveliest chicks or ducks. The low death rate of Hall-Hatched Stock make it worth more and cost less.

Weber Brothers, the famous growers of Pekin Ducks, Wrentham, Mass., whose Hall Incubator capacity is 16,200 eggs, after using Mammoths of two other types, write under date of June 24, 1914:

"We are pleased to recommend the Hall Mammoth Incubator in every particular as the most reliable hatcher we have ever used. *During the present season our hatches run 71% to 85%.* We shall double our capacity, and you may look for our order when the rush is over."
WEBER BROTHERS.

How big is your cellar? What size incubator can you use? Do you want ideal cellar plans? Our Service Specialist will call and help you, if you request.

PUBLISHER'S DESK

The receipt of several letters to this department without the signature of the writers causes us to notify subscribers again that such communications will not be printed. The full name and address of the writer must accompany every inquiry to secure attention. The name of the writer will not be printed, but no attention can be given to letters signed only by initials, "a subscriber," etc.

How will the enclosed do for your Publisher's Desk? This is one of about a dozen received. Why I should be one of the selected for this killing I do not know. Maybe you can save some of your subscribers from this. It looks like a fake.
New York. J. W. C.

The literature enclosed is an offer of the Thwing Co. of this city, offering what is represented to be a $600 lot in Garden Hill for $202.50. We do not know where Garden Hill is located, but we think our subscribers have had sufficient warning already regarding the Thwing Co. schemes that none of them will be tempted to jump at this piece of alluring bait. We hope that no one will be deceived by the seductive offers of the Thwing Co., which are requested to be kept strictly confidential.

Add my name to your list of fraud exposers. This duty of every honest citizen must not fail for lack of energy. The press is our business and social platform. Fraudulent advertisements represent holes in the platform and we can find a solid foundation or platform only in the papers that reject that kind of advertising. M. E.

The Anti-Fake Club is steadily growing in numbers and importance. The formal organization will be made early in the Fall. In the meantime those who want to register as charter members may send in their names. The purposes of the club will be fully outlined when the organization is perfected, but in a general way its functions will be to keep its members advised of fake advertisements and the papers that publish them; and to refuse to receive the papers that persist in carrying fraudulent or deceptive advertising.

I am renewing for another year. I hardly know my reason, as most of THE R. N.-Y.'s contents are foreign to my business, yet I have found much of general interest to my family and myself, and nothing to condemn. J. B. P.
Connecticut.

Unconsciously this letter expresses the success of an ideal we have had in mind for THE R. N.-Y. We refer to a breadth of information and discussion combined with a broad human int rest that would be of benefit and value to all classes of people, and particularly suited to the business requirements of the farmer, and the social and intellectual ne ls of himself and family. Perhaps this ideal of the paper has not been well sustained. We know that for many reasons which have been as yet beyond our control, it has fallen short of our ambition; but it is an encouragement to know that our purpose has met with some success; and we hope to make this feature more conspicuous as the years multiply on us and the means enable us to do so.

Mr. H. D. Braeutigam, who represents himself as a breeder of Barred Rocks, at Greenwood Lake, N. Y., but who wrote me from Newark, N. J., ordered 116 eggs for hatching during the month of February, enclosing check in payment of the eggs, with instructions to ship promptly. I wrote Mr. Braeutigam of the danger of shipping eggs at that season of the year, and as the weather was cold at that time I held the shipment for two days, when the weather moderated. The weather again turned suddenly cold after shipment was made, and Mr. Braeutigam claims that the eggs arrived at Newark in zero weather. He stopped payment on his check and has never reported on the fertility of eggs, which I guaranteed 75 per cent., and I have been unable to get any settlement in the meantime. Can you help me in the matter?
Virginia. MRS. W. D. D.

We took this complaint up with Mr. Braeutigam promptly and he makes an indefinite statement in reply to our letter that the effects of the cold weather destroyed or so weakened the fertility of the eggs that most of the chicks died in the shell. Mr. Braeutigam does not state how many chicks actually hatched from the eggs, but he goes on to say that the chicks had white diarrhœa and communicated the disease to his other chicks, causing him serious loss. Our reports show that Mr. Braeutigam is a minor, so that regardless of any other consideration no legal redress can be obtained. We have a great many complaints for one cause or another regarding transactions over eggs for hatching, and this case illustrates that all the cause for complaint is not on the side of the purchaser. Mrs. W. D. D.'s experience in this case also illustrates that it is not always safe for the seller to assume that he has his pay for the goods ordered when a check accompanies it; certified check or post office money order is better security.

In 1912 I purchased 10 shares of stock in the Union Motor Sales Co. of Dayton, Ohio, with the understanding that I was to take the agency for my territory, and receive 7 per cent. annual dividend from my investment, also that I was to get supplies for my individual use, at dealers' prices, and the goods to be delivered within a reasonable length of time. Soon after my investment in the company I gave them a small order for some repairs that I knew I would need from time to time. I had to write them a number of times before I got them to send them out, and when they did come they were marked C. O. D., notwithstanding that I sent them cash with the order. However, I got them to right this, and just supposed that it was the fault of some careless clerk. But, during the early part of this year (1913) I decided that I could get my repairs from a local dealer just as cheap and get them just when I needed them, so wrote the Union Motor Sales Co. and asked if they would buy my stock and give me in exchange for it some repairs that I was going to have, and they would not make me any reply, notwithstanding I wrote them several letters, registering some of them. After this I decided to try them with another order, so ordered a couple of tires from them; these they sent, after some delay, but on their arrival only one tire was according to order. The other, while I could not use it just then, I knew I could use later, so on June 27, 1913, I sent them another for two other tires. They wrote me that the make I ordered had advanced in price, and I would have to remit a certain amount more, or they could furnish me with other standard makes at the price I remitted (naming the makes), so I advised them to send either of the makes they had named, but to get them to me within a certain time or refund money. Thus I waited for nearly a month expecting every day that the tires would show up; finally I wrote them about it, but no reply came. This letter I followed with others, several of them being registered, but no reply came until I threatened to take legal steps; then they said they would look into the matter, but as yet I have gotten nothing out of them. I have, as best I can, explained the situation to you, so please advise me whether or not you can do anything with this matter. R. S.
Georgia.

After considerable correspondence with the Union Motor Sales Co., above referred to, we secured for the subscriber a check refunding the remittance he sent the firm for the tires, which, it was claimed, had been lost in transit. The check, however, was only signed by a rubber stamp. We returned it to the company for a proper signature, but have never been able to secure the proper signature of the company to the check. In the meantime the Motor Sales Co., which it is alleged was a Maine corporation, is in liquidation, and the Union Motor Co. of Dayton, Ohio, has been organized under the Ohio State laws to take over and carry out all contracts with the members and dealers of the Union Motor Sales Co. The new company proposes selling membership certificates, instead of stock certificates which were sold by the old concern. The experience of the above subscriber only bears out our experience with these stock selling and membership selling schemes generally. The stocks and memberships are sold with the idea that the investor can then buy goods from the company cheaper than elsewhere, but as this subscriber eventually found to be true, goods of an equal grade can easily be purchased in the open market at the same or a lower price. Eventually the money paid for the stock, or certificate, is usually lost, as in this case. It will be well for the readers of THE R. N.-Y. to remember this subscriber's experience when approached by a slick-tongued agent on a stock or membership scheme of this sort or when in receipt of literature of the promoters.

Small Pens; Beef Scrap.

I HAVE a henhouse 20x6 feet. I wish to make it into separate pens for 10 fowls each. I think usually houses are made wider, but if I make the house wider it leaves too much floor space, more than I wish to pay for, or make it too narrow on the front. Will my fowls get along just as well to divide the house up into four pens five feet wide and six deep? 2. I feed dry mash, but find that with beef scrap in it the fowls spoon out a lot and waste it looking for scrap, so I am feeding dry mash in hoppers and beef scrap separate. How much beef scrap should I allow for 100 hens per day? E. R. S.
Virginia.

Unless you have some reason for wishing to keep your fowls in small flocks, it would be better not to divide your little house into pens. With four pens, each fowl would have but 30 square feet of floor space to use, while with no partitions each one would have the liberty of 120 square feet. If they have the use of a good sized yard, the amount of floor space in their house is of less importance, but if they are confined, their quarters are pretty small.

2. A dry mash hopper should be so made that the fowls cannot spoon the feed from it. The opening through which the fowls feed should have an inwardly projecting lip to catch and hold the mash, or it should be guarded by slats or wire mesh in such a way that the fowls cannot flirt their beaks while eating. If the scraps are fed alone, there is nothing to prevent the fowls from eating too much scrap to the exclusion of other food.
M. B. D.

Chicks With Foreign Markings.

I RECENTLY bought 100 baby chicks. These chicks were advertised as purebred S. C. White Leghorns, Barron-Young cross. I notice these chicks have dark spots on them or black feathers. Is this possible with purebred White Leghorns? J. C. C.
Ohio.

Yes, it is possible for purebred animals of any kind to show markings foreign to their breed. At some more or less remote period in their ancestry they were all mixtures and with some breeds this period is not very remote. As a consequence, this ancestral blood will at times crop out, like an inherited taint, and those not acquainted with this possibility are sometimes led to accuse a breeder unjustly. The crossing of two separate strains of the same breed sometimes seems to intensify this liability to "throw back" to ancestral traits. M. B. D.

EGG-EATING HENS.—I have noticed articles of late about a cure for egg-eating by hens. My remedy, which has never failed me, is to make an opening carefully in large end of egg and mix in as much red pepper as possible. Put shell back carefully. If taken at the start there is usually just one guilty hen. Watch for her and when found put her in small coop with the treated egg. She will take just one taste and will never try to eat another egg.
New York. E. R. WATSON.

Cuts silage evenly
Packs better—lasts better—makes better feed
The knives of the Blizzard make a clean, shear cut and the silage is cut slick as a whistle, in even lengths, from ¼ to 1½ inches. Silage cut by a
BLIZZARD
Ensilage Cutter
packs better, keeps better, and, according to our customers, makes better feed, increasing milk yield and butter fat.
OTHER GOOD POINTS
of the Blizzard are: Light running—any farm engine runs it. Eats up silage fast as you can feed. Easily fills highest silos. Simple, safe and durable. Self-feed table.
New catalog tells whole construction.
Write for it now, before you forget.

"Ohio" 1914 Model
The Improved Logical
Silo Filler

"Ohio" improvements for 1913 were radical—and with marvelous results.
Don't close a deal for *any* Cutter and take chances with unknown makes until you see what the "Ohio" offers.
59 years' experience—*absolutely dependable quality.*
Famous Direct Drive
The machine that is driven, cuts and elevates *direct* from main shaft. Simple, compact—low speed fan—*non-explosive—non-clogging* on any cut. Cuts *clean* on all crops—knives can't spring.
One Lever Controls All
Entire feed reverses by *wood friction* at finger pressure—no strain—not a gear tooth changes mesh. All gears perfectly housed. Famous "Bull-Dog" grip self-feed. Enormous *half-inch cut* tonnage, 50 to 250 tons a day—6 to 15 h. p. 20-year durability. Used by Experiment Stations everywhere. Guaranteed. Many big new features this year.
Write for free "Ohio" folder today, also "Silo Filler Logic." A postal will do.
"Modern Silage Methods" a 264-page book mailed for 10c, coin or stamps.

Salem, Ohio

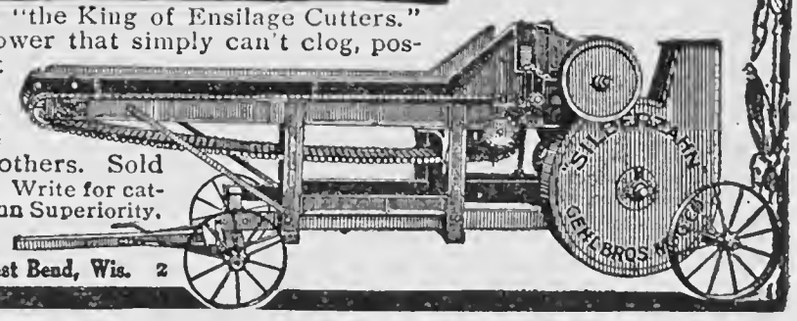
Harder Silos

Catalog Free
For 15 years the one Best Silo. Great improvements this year—better than ever. Solid as an oak; owners now laugh at storms. More durable than concrete, more profitable than tile. Massive strength, surprising solidity, perfect fitting and easy operating doors. The kind "Uncle Sam" uses.
It will pay you to write us today for free catalog of Harder "Quality" Silos.
Harder Mfg. Co., Box 11, Cobleskill, N.Y.

Fill Your Silo Pay when Satisfied
Over 64 Years Experience Back of it.
ROSS Machines are fully guaranteed
You take no risk

Oldest and Largest in the World
We want to prove that our machines are a good investment before you give up your money. We know they are so good that we do not feel it a risk to make this offer. Many new features have been added which you should know about. Special made machines for New York State and the East. We make many styles and sizes to meet any and all conditions. Write for catalog
The E. W. Ross Co., Box 113, Springfield, O.

Wrought Iron Pipe—of sound, second-hand quality, with new threads and couplings, 14-foot lengths and up. Also pipe cut to sketch for fences, or drilled for irrigation purposes. We guarantee entire satisfaction or return money. PFAFF & KENDALL, 101 Foundry St., Newark, N. J.

Solid, Light Running Machines With An Awful Appetite
—that's the way one owner describes the "Silberzahn." This same owner says: "If I had to buy a dozen ensilage cutters every one would be a Silberzahn." Hundreds of other owners say substantially the same thing. It's strong, powerful, safe, economical—that's why the
Light Running Silberzahn Ensilage Cutter
has been rightly called "the King of Ensilage Cutters." Has a throat and a blower that simply can't clog, positive safety device, best knife adjustment, strongest built frame and other valuable features not found in others. Sold under positive guarantee. Write for catalog and proof of Silberzahn Superiority.


Gehl Bros. Mfg. Co.
134 S. Water Street West Bend, Wis. 2

Fills Your Silo Quickly With Less Power and Labor
You can operate this machine with a 4 h. p. gasoline engine. It's the lightest running blower type of ensilage cutter made—The *throwing, blowing, lifting force* carries the ensilage in a steady full stream rapidly up into the highest silo without waste of power. The ensilage packs perfectly and keeps sweet and succulent. The
PAPEC ENSILAGE CUTTER
is easy to set up and take down. Simple in construction, not easy to get out of order. The entire frame is one solid piece of semi-steel. The bearings are always in line, run smoothly and will not heat. The feeding mechanism is geared to the main shaft—always gives you the desired length of cut. The *Papec Ensilage Cutter* is not chain driven, but has heavy gears which transmit *all* the power. It cuts ensilage perfectly and swiftly—as fast as you can bring the corn to the machine.
Write for Illustrated Catalog. Send today for this book. It shows how The "Wonderful Papec" cuts ensilage with less power, time and labor.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending July 24, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914.	1913.
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.51 and $1.41 for B and C. Hotels and restaurants using two to three cans per day are paying 4½ to five cents per quart single quart prices from bakeries and grocery stores, six to seven cents; delivered milk, nine to 10 cents.

BUTTER.

The price closes one cent above last week, with a fairly firm market on the better grades. A great many of the receipts show hot weather damage. This is the fault of both creamery patrons and the butter-makers, but the latter are helpless without co-operation of the patrons. Keeping the milk and cream in best condition during torrid weather makes a little more work, but the extra care is quite sure to be rewarded in improved price of the product and satisfaction of buyers. City butter, made from surplus milk, is selling at 20 cents or under.

Common to Good	18	@	23
Factory	16	@	20
Packing Stock	16	@	19

Elgin, Ill., butter market 27¼ cents.
Philadelphia, western creamery, 28½ cents.

CHEESE.

The demand for whole milk specials is active. Large quantities of undergrades and skims are going into cold storage because of surplus and unattractive prices. Some small sizes, Daisies and Young Americas, have sold up to 16½ cents, but the main range of prices runs the same as last week.

Whole Milk, fresh, specials	14¾	@	15
Average fancy	14¼	@	14½

Parmesan	25	@	28

EGGS.

The top grades have been down and up one cent, prices at end of week remaining on same basis as last reported. The threatened strike of New York egg candlers for shorter working periods and recognition of the union has not occurred, and is evidently more talk than powder. The egg candler is a necessity in large trade, but it is a business in which reasonable commercial efficiency can be learned quickly, so that a strike is likely to inconvenience the strikers more than the dealers.

FRESH FRUITS.

Some improvement is noted in the new apples received, good hand-picked bringing up to $3 per barrel, prices ranging from this figure down to 50 cents. Peaches remain low, $2 per crate being practically the top wholesale figure, and large quantities of fair quality going under $1.50. Currants in considerable surplus and low; other small fruits selling well unless damaged by weather or transit. Muskmelons going at a very wide range of prices—35 cents to $3.25 per bushel. The high priced ones are those running uniform in quality, the result of good cultural treatment and seed selections, mainly the latter. The late L. M. Lyon was a pioneer in educating melon producers to the importance of using best seed. His vigorous work in the Western fields, where he cut the best melons for seed, was at first startling waste to the growers, but they very soon saw the point and were glad to use the selected seed at high prices. Of course, blight can spoil any muskmelon, but some of the low quality laid to blight is the result of using seed from cull melons.

VEGETABLES.

Early in the week potatoes were in heavy surplus, but these were cleared out and prices improved somewhat at the close. Onion market unsettled because of heavy receipts of unripened stock from nearby. Receipts of string beans and peas excessive, and prices low except for the best. Corn plentiful and lower, good Hackensack wholesaling at $1.50 to $2 per 100. Lettuce again very low. Tomatoes higher, $2 to $2.25 per box being had for choice Jersey Acme and Stone. Nearby cucumbers selling well; Maryland and Delaware pickings low.

*

A steamer leaving Brisbane, East Australia, April 27, is unloading about 3,500 tons of beef, lamb and mutton at New York. The steamer stopped at Uruguay for a shipment of beef, but most of the meat came from Sydney and Melbourne, Australia. This is the third recent steamer with direct meat shipments from Australia to New York, more than 13,000 miles.

*

An item, about two stickfuls long, is making the rounds of a large number of newspapers. It is almost identical, both in statement and tone, with items seen last year and the year before, and the tenor of them all is that meat will be higher. Quite likely they will, as it is in the power of those controlling the meat situation to jack up prices. This little item is part of their "campaign of education." The consumer reads it, draws a long breath and prepares for the worst, and many jobbers and retailers take advantage of the suggestion to the limit. As will be noted in the quotations given above, it is possible to get good meats at moderate prices in New York if the buyer looks about a little and will carry his purchases home instead of having them delivered.

W. W. H.

The FARMERS' BUREAU an agency exclusively for agricultural help. Only first class farm help and positions solicited. References investigated. Scientific advice on farm problems. Dept. R, 150 Nassau St., N. Y. Phone, 5565 Beekman

50% Sacrifice to Close Estate—195 acres of the best valley land in New Jersey, all under cultivation. 2 miles from 2 R.R. stations on macadam road. 68 miles from N. Y. City. It cost deceased owner $136 an acre. $68 an acre will buy it with buildings. E. E. SLOCUM, 141 Broadway, New York City

DO YOU NEED FARM HELP

We have many able-bodied young men both with and without farming experience, who wish to work on farms. If you need a good, steady, sober man, write for an order blank. Ours is a philanthropic organization and we make no charge to employer or employee. Our object is the encouragement of farming among Jews. THE JEWISH AGRICULTURAL SOCIETY, 176 Second Avenue, New York City.

Subscribers' Exchange

MAPLE COVE FARM—Products direct to Consumers. ROUTE 24, Athens, Pa.

FOR SALE—Newtown Colony Brooders; demonstration machines, practically new; bargains. JUSTA POULTRY FARM, Southampton, L. I.

EARLY RICHMOND CHERRIES canned on the farm in No. 2 sanitary cans; $1.25 per doz.; syruped with pits. SENECA FRUIT FARM, Waterloo, N. Y.

FOR SALE—Power Greenbone Cutter; perfect condition, self feeder; also five International hovers; bargain; wanted, Climax box brooders. MONTICELLO EGG FARM, Monticello, N. Y.

FOR SALE—"Perry" Compressed Air Water system; consists of Fairbanks air compressor, new engine, one Perry pump, air tank and quantity of pipe; in first class condition; also one small size "Niagara" ram; price reasonable; might exchange. F. N. GIDDINGS, Baldwinsville, N. Y.

FARM FOR SALE—Four acres of strawberries, two grapes; nice chicken range. Box 1, North Emporia, Va.

TWELVE ACRES—Good land; house, barn and tools; $1,200; $400 cash; easy terms. E. BALCOM, Castile, N. Y.

FARM—For rent on shares, with some stock; possession at once. W. H., care R. N.-Y., 333 West 30th St., New York.

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

WANTED—A good, steady man for general farm work; must be able to drive a team; a steady job; $30 per month and board. M. N. ADAMS, Livonia, N. Y.

WANTED—October 1, settled Protestant woman for general housework in small village, winter resort section; small family, good home. Drawer J., Aberdeen, North Carolina.

POSITION WANTED—On farm, by married man, 40; family; life experience; capable of taking any position, or taking charge; best of references. W. A. MAYOR, Jermyn, Pa., R 1.

WANTED—Situation on dairy farm; begin work August 20; good milker and teamster; understand farm machinery; references. F. C. V., care WM. SHORT, R. R. 3, Canajoharie, N. Y.

WANTED—Sober, industrious man, experienced with horses, milk two cows, help in garden; $50 per month; no graduate; must have references. WILLIAMSON, Lombardy St., Lancaster, N. Y.

WANTED—Single man for general farm work; must be strictly sober and honest; good milker; wages $25, board and washing; send reference in first letter. H. H. MEADER, Supt., Oakhurst Farm, Millerton, N. Y.

POSITION WANTED—As manager for farm or estate; would take good dairy farm on shares, thoroughly understand farm crops, up-to-date machinery, steam and gasoline engines, tractor plows, concrete work; New York State preferred; strictly sober, reliable, married American; small family; good references. Address Energetic, Care R. New-Yorker.

A METHODICAL, practical, scientific and successful general farm and dairy manager covering years of extensive and varied experience in exacting operations will be open for engagement Sept. 1. Eminent credentials will be furnished and nothing short of a first-class, responsible and remunerative position will be considered. If desirous, might consider cash proposition of lease of entire property. Address T. J. A., care Rural New-Yorker.

WANTED to lease, with the privilege of purchase, small poultry farm; north Jersey preferred. C. B., Rural New-Yorker.

FOR SALE—Good, productive 160-acre farm; good buildings and location; fine lot of timber; a bargain. Address Box 65, Route 1, Oxford, N. Y.

FRUIT, TRUCK, POULTRY FARM—Will sell all or any portion of 36 acres; good buildings, excellent location; immediate possession; no agents. HOMER TWEED, Quakertown, Pa.

TO LET ON SHARES—A well-equipped farm of 165 acres, half of it in cultivation in Bergen County, N. J., adapted to dairying, pig raising or truck farming. M. N., Rural New-Yorker.

LARGE EGG FARM—Tributary to New York; equipped, stocked, doing large business; offered because of ill health; part cash, balance mortgage. Address JAMES MAXWELL, Fiuderne, New Jersey.

FOR SALE—Farm of 100 acres; another of 50 acres; one of 33 acres; near Wolcott, N. Y.; new buildings; large apple orchards and some muck land; come and see, or write to A. H. CREQUR, Wolcott, N. Y.

FOR SALE—265 acres A No. 1 land, for stock, fruit, or general farming; well watered; beautifully located; double house, three large barns and other buildings. C. H. HERENDEEN, owner, Shortsville, N. Y.

FOR SALE—Successful poultry plant, location convenient to market, modern equipped buildings housing 900 hens; must be seen to be appreciated; price reasonable; terms. Address BARGAIN, care Rural New-Yorker.

COMMUTERS DAIRY OR STOCK FARM; 31 miles N. Y. C.; express station; 114 acres; hill, rolling and wood, river; grand situation; large house, improvements, up-to-date barns, silo, stock, crops, machinery, complete $300 an acre; terms. H., care R. N.-Y.

POSITION WANTED—On fruit farm, 25 years experience in apples, from planting to marketing; understand and can operate all kinds farm machinery, gasoline and steam engines; total abstainer from all intoxicants and tobacco. Permanent position wanted where quality counts. Address L., 333 West 30th St., N. Y.

FOR SALE—Pleasant View Dairy, 130 acres; one of the best farms of its size in Bedford County; good buildings, lawn, splendid shade. Land lies well, is adapted to all kinds of fruit, vegetables and grass, convenient to high school, hotel, stores, churches, and the best of neighbors; good home market. Address owner, F. W. SHAW, Forest Depot, Va., R. F. D. No. 1.

A BARGAIN—112-acre Hudson River Valley farm, Ulster County, New York. One mile from West Shore Railroad station and village of 4,000; suitable for fruit, poultry or general farming; 2,000 fruit trees, 3 to 10 years in bearing; lots of small fruit; one acre of strawberries; old-fashioned 12-room house in good condition; barn, stabling 16 cows and 6 horses; poultry house, granary and all farm implements; springs and wells; to quick buyer, $4,000. Address MORTGAGEE, Box 97, Madison Square, P. O. New York.

SHERMAN SQUARE HOTEL

Broadway (Block Front) 70th and 71st Sts., New York

Express subway station at door. Most convenient location uptown. A residential hotel away from all the dust and noise of busy sections and yet in point of time downtown.

Rooms with use of bath, $1, $1.50, $2 and $2.50
Rooms with private bath, $3.50 and upward
Suites in 2, 3 and 4 rooms with bath, furnished or unfurnished, by day or annual lease

Write for further information or reservations.

HUMOROUS

BOBBIE (who has been sent over for the fifth time to find out how Mrs. Brown is): "All right, ma; she's dead."—Baltimore American.

"HAVE you any taste for eugenics, Mrs. Comeup?" "I've never tried 'em. Do they taste best fried or boiled?"—Baltimore American.

JAIL VISITOR: "You say that a love for books brought you here, my poor man." Prisoner: "Yes, mum; pocketbooks."—Boston Transcript.

"WHERE do you live?" was asked of a childish newcomer to a quiet village. "Oh, I don't live," was the ingenuous answer. "I just board." Chicago Recor Herald.

"WHAT'S that new structure you hav put up on the hill there?" "Well," r plied Farmer Corntossel, "if I rent it, it a bungalow. If I don't, it's a barn."— Washington Star.

BIX: "Wasn't it Admiral Porter wh said, 'Take no quarter from the enemy'?' Dix: "Dunno! If it was, he's the onl porter that ever said such a thing."— Boston Transcript.

PASSENGER: That last station was my destination, sah. Why, sah, didn't you stop thar? Conductor: We don't stop there any more. The engineer's mad at the station agent.—Sacred Heart Review.

HE: "The President has given those mediators to understand that he can't recognize Huerta." She: "How stupid; why, I would recognize him anywhere from his pictures in the papers."—Birmingham Age-Herald.

HE (calling): "I fear I must seem like a Sahara of dullness this evening, Miss Edith." She: "Oh, no, Mr. Timmid, you are not at all like a desert; a desert has sand."—Boston Evening Transcript.

"YOU do not speak to him?" "No," replied the scholarly girl. "When I passed him I gave him the geological survey." "The geological survey!" "Yes. What is commonly known as the stony stare."—Washington Star.

THE fifth day drew to its close with the twelfth juryman still unconvinced. The Court was impatient. "Well, gentlemen," said the court officer, entering the jury room, "shall I, as usual, order twelve dinners?" "Make it," said the foreman, "eleven dinners and a bale of hay."—Credit-Lost.

"WHO are those two sad-looking women over there?" "They're a couple of neighborhood women who always get together to mourn." "Torn by some common sorrow?" "Yes, one's husband never comes home, and the other one's husband hangs around home all the time."—Houston Post.

OLD Uncle Andy was steering his master's boat down the bay. They passed an ocean liner. "Andy," said Mr. Blank, "just look how high that ship stands out of the water. I wonder why it is." "Why, boss," answered the old darky, "don't yu know? We ain't had no rain for nigh on three weeks now, and de water's gettin' low."—N. Y. Evening Post.

HARRY, a bright youngster, was told by his mother that she would give him five cents for a dozen pins rescued from the floors, thus preventing her year-old babe, who was just beginning to creep, from finding them. "What will you do with the money when you earn it, Harry?" he was asked by a neighbor. "With the first five cents," said Harry, "I will buy a paper of pins and scatter them all over the house."—National Monthly.

Things You Get Extra In No-Rim-Cut Tires

1 Extra Tire in 4

Goodyear tires now undersell 16 other makes. That is due to mammoth output—the largest in the world.

Numerous tires cost one-third more. You can buy four Goodyears for what three of such tires cost. That means to you one extra tire in four.

Or Extra Size

Or you can do this:

You can buy a half-inch wider Goodyear for less than some makers charge for smaller sizes. And the wider tires will fit your rims.

The same rims will take

A 30 x 3½ or a 31 x 4.
A 32 x 3½ or a 33 x 4.
A 34 x 4 or a 35 x 4½.

So with other sizes. The larger size has, on the average, 20 per cent more capacity. It has an extra ply of fabric. It has a thicker tread. It means far more mileage, far less trouble.

Yet the price men pay for many tires buys this half-inch wider Goodyear.

Four Extra Features

You get in Goodyear No-Rim-Cut tires the best tires men can build. A better tire, so far as known, is utterly impossible.

You get the tire which outsells any other, after millions have been tried.

And you get these four great features found in no other tire:

No-Rim-Cut feature—which makes rim-cutting impossible.

Our "On-Air" cure—an exclusive, costly process which saves all the blow-outs due to wrinkled fabric.

Our rubber rivets—hundreds of them are formed in each tire to combat tread separation.

All-Weather treads—the tough, double-thick anti-skids. Flat and regular, so run like plain treads, yet they grasp wet roads with deep, sharp, resistless grips.

Those four great features—used by us alone—have saved tire users millions of dollars.

Reinforced Inner Tubes

You get another extra when you buy the Goodyear Reinforced Tubes. Where the pinching comes which ruins most tubes, these are heavily reinforced. They are made of pure rubber—never colored. Colored rubber must always be alloyed. The extra thickness means 30% more rubber than most inner tubes.

Any dealer, if you ask him, will supply you Goodyear tires and tubes.

VOL. LXXIII, No. 4267. NEW YORK, AUGUST 8, 1914 WEEKLY $1.00 PER YEAR.

MAKING COMMERCIAL POULTRY PAY.

Getting Rid of Drone Hens.

SELECTING LAYERS.—After the high Spring egg production on large commercial poultry plants where White Leghorns are kept, there are always a number of hens and laying pullets that are not paying their board. This is the time for the first selection of all laying stock. I usually make this selection about the first week in June. The hens culled out are either broody, starting to molt, or have just stopped laying, and should be sold at once for the following reasons: In April and May any hen that becomes broody is sold. Broodiness is a character not wanted on commercial poultry plants, as hens do not produce while broody. Also, no hen that has been broody should be used as a breeder. This character should be bred out as much as possible.

UNDESIRABLE CHARACTERISTICS.—Broody Leghorns may be cured, but the egg organs have become absorbed to such an extent that it would take three weeks or more to get the hens back in good laying condition, and after they are laying again, the profit from the Summer eggs they would lay will not, in most cases, pay for the food eaten while broody and labor curing broodiness.

EARLY MOLTING.—An early molting hen is always a poor producer. Early molting shows the hen has not the vitality that is necessary to make a high yearly egg production. As it takes a hen 80 to 104 days to complete the molt, she is being carried through the Summer at a loss. Any hen that starts to molt before the first of September should never be used as a breeder. Here at Broad Brook Farm I do not keep any hen that starts to molt before the last of September.

OTHER QUALITIES.—In all plants there are a number of hens that break down or just stop laying. These should be sold at once. Other very important factors in selecting and breeding are size, weight and shape of hens and cockerels. If one selects and breeds for egg production only, and does not consider these factors, he will in time defeat his own purpose. Here when I made my final selection of breeding stock, in November 1913, no hen that did not weigh 3½ pounds and over, or cockerel 4½ pounds and over was kept. This year I shall make the standard even higher, thus increasing weight.

SOME PROFITABLE YOUNG STOCK. FIG. 419.

HEAVY FOWLS DESIRABLE.—By raising only large and heavy Leghorns, the broody, molting and other cull hens can be sold at top market prices alive in New York City; whereas small hens sell considerably under top prices. This factor makes a great difference in the year's profit account. From my experience, the large Leghorns properly bred and selected will produce as well as the small ones, and they certainly are more profitable on a commercial plant.

SUMMER SELECTION.—Not only should all laying stock be gone over the first week in June, it also should be gone over in July, August, September, October, and the final selection of breeding stock be made in November. All cockerels should be sold just as soon as the breeding season is over, not only to save feed, but to have only sterile eggs to sell during the Summer.

RESULTS OBTAINED.—I will give you an example of the results of this method of constant selecting of laying stock: On June first we had here 1962 laying hens in our long house; egg production 927 eggs. Between June first and tenth we sold 410 hens; after the tenth 124 more, making a total culled out and sold of 534. To these must be added 15 that died in June, leaving in the long house, July 1, altogether 1413 laying hens. Total egg production for June 25,599; average daily production, June, 853 eggs. Egg production July first 910 eggs. Between July first and fifteenth sold 106 hens. The total egg production to July 20 was 15,619 eggs. Average daily 822 eggs. You see from the above that while the egg production has decreased each month as the Summer advances, the feed bills have decreased in proportion. Also, by selling so early in the season the price per pound was always two to three cents higher. This method I have used for a number of years with the same excellent results. Keeping down expenses is a most important factor in making a plant pay.

Egg production for 1914, January to July 20: On hand January 1, 1914, 750 selected, late-molting, breeding hens each weighing 3½ pounds and over. 1691 laying pullets. Total laying stock 2441 hens. 54 cockerels each weighing 4½ pounds and over.

DATE	LAYING STOCK	EGG PRODUCTION	DAILY AVERAGE	PER CENT.
January	2441 to 2398	10150	327.4	13.5
February	2398 to 2349	17574	627.6	26.4
March	2349 to 2298	36004	1161.4	49.9
April	2298 to 2196	41536	1384.5	61.6
May	2196 to 1962	38806	1251.8	60
June	1962 to 1413	25599	853.1	
July 1-20.....	1413 to 1307	15619	822	

The percentage of egg production is figured on the number of hens, half way between the largest and smallest number for the month. This shows as a discredit to the hens as most all were sold before the 15th of the month. Before June 10th over 400 were sold, so I have not figured the per cent of egg production for June.

E. H. PARSONS.

Westchester Co., N. Y.

A DISCUSSION OF LIGHTNING.

WHAT IT IS.—Nature furnishes few more awe-inspiring and spectacular demonstrations of her tremendous natural forces than in the zig-zag forks of lightning which dart across the clouds of a sultry Summer sky; nor is their awful effect lessened by the crashing and rolling of the thunder which accompanies them. The phenomena attending these discharges from nature's huge storage batteries are not yet fully understood, though they have been the subject of much study. Fortunately, however, we have a better understanding of the methods of control of electrical energy than we have of its essential nature and electrical engineers present the somewhat peculiar spectacle of workmen rearing great structures with tools which they have never seen and whose form they do not know. We know that electrical energy is a force which exists all about us in nature, and that bodies may be charged with it as a sponge may be saturated with water. The earth itself is one of these bodies, and the clouds floating above it are others. This electrical energy is a restless thing, ever in motion, and if it consents to remain stationary for the moment in some electrified body, it is always straining at its leash, ready to leap forth at the first opportunity.

MANNER OF DISCHARGE.—Several ingenious theories have been advanced to account for the storage of this energy in the clouds accompanying a thunder storm, and while none can be said to have been proven, we know that the energy is there; we know, also, that the earth is highly charged with the same element. Ordinarily these will be kept apart by the intervening atmosphere, for air is a poor conductor of electricity and it would prefer not to travel through it. The time may come, however, as it frequently does on a hot Summer afternoon, when the earth and overhanging clouds become so filled with this electric force that the tension of the stored energy becomes too great for the atmosphere to resist its passage, and seeking to restore the disturbed electrical balance between earth and sky, a charge of electricity of tremendous force darts from a black cloud to some point upon the earth's surface. As

the moisture laden atmosphere resists its passage terrific heat is developed, and the moisture, instantly converted into steam, produces a sudden expansion of the air which, as quickly returning, produces the sudden crash or long roll of thunder which we hear. Not all the lightning flashes which we see are directed toward the earth, for the black clouds frequently hurl their thunderbolts at each other. When they do, they show that the same electrical relation exists between them as also exists between the clouds and the earth. This interchange of electricity between clouds is productive of one of the most destructive forms of bolts which reach the earth. A low-hanging cloud charged to its full capacity sometimes receives a discharge from one above it; this releases a portion of the lower cloud's electrical energy, which then drops to the earth with an explosive force which no human agency can control. From the ordinary cloud discharge buildings may be largely protected, but the terrific force and erratic course of a thunderbolt thus generated is such that artificial conductors have no control over it.

COURSE OF ELECTRICITY.—An electric current, whatever its source, has this much in its nature akin to that of humans; if resisted in its course, it becomes heated. Permitted to flow freely through channels agreeable to it, no disturbance whatever is created, but if compelled to travel paths along which it must force its way a large portion of its energy is transformed into heat, and through the agency of this heat, it wreaks destruction. All known substances are conductors of electricity, but by some it is conveyed freely, while others resist its passage. These latter substances are termed non-conductors, and they are used to insulate or protect conducting bodies from loss of the current which it is desired that they shall carry. Water is a better conductor than wood, so that wood, though a good non-conductor when dry, carries an electric current freely when its pores are filled with water. When a bolt of lightning strikes a branch of a living tree it follows it to the ground, quickly changing the sap of the tree to steam by the intense heat generated, and the explosive force of this steam frequently shatters trunk and limbs. Similarly, the air and moisture contained within the bricks of a chimney are rapidly expanded when struck by lightning, and the chimney is burst apart. Air is a non-conductor, more or less of which may always be found between a person's feet and the ground. If a person is struck by lightning, the current must traverse this air space, and in doing this an explosive force is exerted which often tears the shoes from the feet.

POSITIONS OF DANGER.—The danger zone in a thunderstorm is directly beneath the storm cloud or a little in advance of it. Any object upon the earth's surface is liable to receive a lightning flash, but tall objects projecting toward the sky are in greatest danger. People in fields should not take refuge beneath trees, and proximity to wire fences should also be avoided. Such fences should be "grounded" by vertical wires at intervals of every few rods, crossing the fence wires and extending well into the ground. If generally observed, this precaution would save the lives of many cattle now killed by lightning flashes which travel along fence wires. While it is not necessary within the house to seek refuge beneath a feather bed during a thunderstorm, it is wise to keep away from stoves and fireplaces, for the column of heated air rising from a chimney furnishes a better conductor for a lightning flash than the colder atmosphere about it.

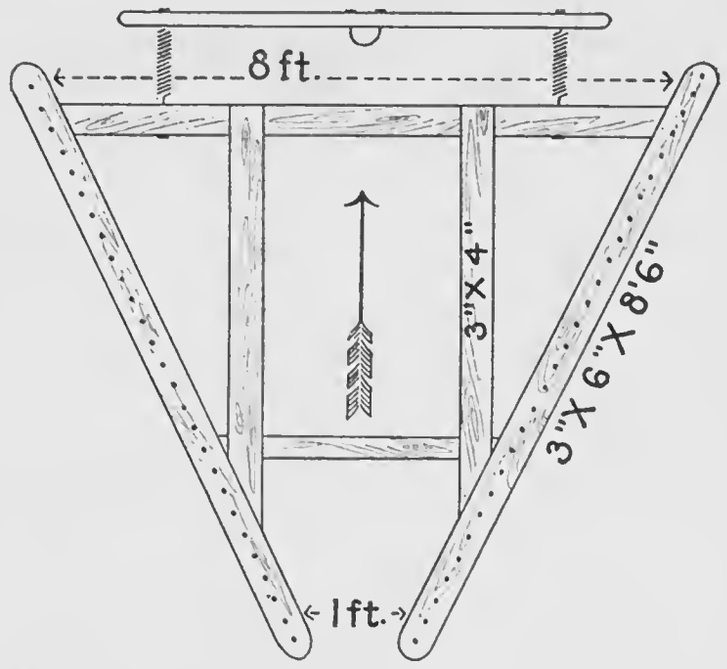
LIGHTNING RODS.—The use of lightning rods upon buildings has markedly decreased in the last 25 years, though it is recognized that when properly installed they furnish a considerable amount of protection. A No. 3 or No. 4 galvanized iron wire carried along the ridge of a building and properly connected with the ground at its sides will furnish a large amount of protection at small cost. This wire should be armed with sharpened points projecting about 20 inches toward the sky at intervals of 18 or 20 feet, and it should be thoroughly grounded by wires extending from it to terminals placed so far beneath the surface of the ground that they will always be in contact with moist earth. Galvanized iron has been found to be better than copper, for while not as good a conductor as the latter metal, it will dissipate the destructive energy of lightning with less danger from induced or side flashes which often set fires, or do other damage, after the main current has been safely disposed of. Such lightning rods not only take care of many direct flashes, but they often prevent them by furnishing a path by which atmospheric electricity may pass quietly into the ground before sufficient tension has developed to result in an explosion. Whether it pays to install a system of lightning conductors is an unsettled question. Good buildings are usually insured against loss from lightning, and most farmers seem to consider the protection of their policies sufficient. Certainly, the ubiquitous "lightning rod agent" is much less in evidence than in former years.

M. B. DEAN.

SOME COVER CROP QUESTIONS.

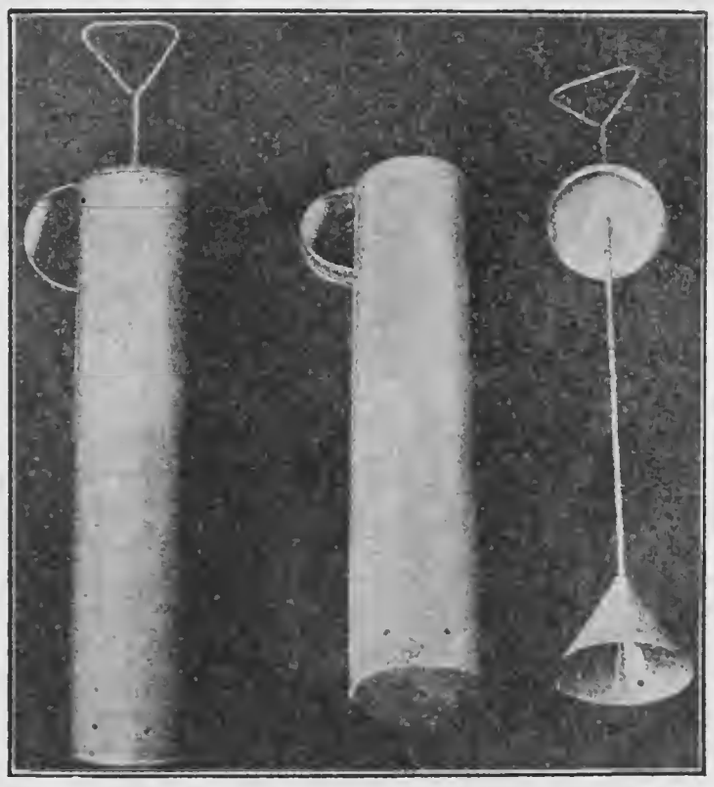
I HAVE a young orchard planted to late cabbage. When the cabbage is cut in the Fall I want to pasture the offal with hogs. I have been thinking of sowing either rye or rape at the last cultivation of the cabbage to make still more green feed. Which will be the better the rye or the rape? Do you think that either might hurt the crop of growing cabbage? S. H.
Ohio.

We should sow rye alone, or barley and rye together, in this orchard among the cabbage. Rape



A DEVICE FOR RAKING STONE. FIG. 420.

would make a heavy growth, and give considerable feed for the hogs, but it would take a good deal from the soil while the cabbage was heading, and we should hardly care to sow turnips, rape or other plants of the same family among the cabbage. A mixture of half and half barley and rye, cultivated in at the last cultivation, will make a heavy growth through the Fall. The barley grows well under such conditions, and would be eaten off by the hogs. They would pasture down the rye, but some of this would be left to make a fair growth in Spring for plowing under. This whole question of sowing a cover crop in among the cabbage depends much upon the season, and personal judgment is required in order to handle it properly. In a dry season, when there is evidently hardly enough moisture for the cabbage alone, it would be a mistake to sow any cover crop among the cabbage. You would simply rob the cabbage crop of moisture, and could not expect enough of a cover crop to make up this loss. In a moist or wet season, however, there will be water enough for both crops, and in such a case the cover crop will pay, as



OUTFIT FOR MAKING AN EMULSION. FIG. 421.

it would help instead of injure the cabbage crop, give a large amount of pasture for the hogs, and save the loss of nitrates from the soil.

I have another field of four acres. It is sandy land. It has been in truck crops, cabbage and potatoes for four years. It has produced abundantly. The land produces too well to sow to wheat, corn, oats or clover, if the fertility can be kept up. During the four years it has had three dressings of manure and considerable fertilizer. If I can harvest the crops early enough this Fall I wish to sow this field to rye to plow under next Spring. If I cannot sow it to rye this Fall how would it be to sow it to cow peas early next Spring to plow under in June for a crop of late potatoes? I wish to keep up the fertility of this field without having to plant it to field crops. Will my plan do? S. H.
Ohio.

We would sow this field to rye, even if we had to wait until the middle of October or later. It will be a mistake to sow cow peas early next Spring. The cow pea is not a Spring crop; it is a hot weather plant which makes its growth during the warmer part of the Summer. It is as tender as a bean, and if seeded in the early Spring it usually decays in the ground, and proves a failure. The crop that you want for early Spring seeding is the Canada field pea, which is a cool weather plant, and does well when seeded early. We should sow Canada peas and oats together, as is often recommended for producing a fodder crop. Let this grow until the middle of June, or until you want to plant your late potatoes. Then plow this crop under and fit the land. This will add a large quantity of organic matter, and also some nitrogen from the Canada field peas. For potato growing it will be necessary to use some fertilizer in addition to the cover crops.

MAKING AN EMULSION.

THE picture at Fig. 421, taken from Bulletin 106 of the Tennessee Experiment Station at Knoxville, Tenn., shows the appliances for making a kerosene emulsion or similar mixture which requires thorough mixing or churning. As will be seen, there is a tin vessel 18 inches long and four inches in diameter, with a plunger such as is used on some farms in washing machines. This plunger has a row of holes in it and is connected with an iron rod so that it may be churned up and down through the cover. The liquid to be mixed or emulsified is put into the tin cylinder, and then this plunger is put in and churned up and down until the mixture is made. This bulletin contains recipes for making applications to animals or plants. Among others is the following treatment for animal parasites such as ticks, hen lice and stable flies. This stuff is made by heating cottonseed oil, sulphur, potash and beeswax until the beeswax is melted. Then add three gallons of cottonseed oil or fish oil. Add one part of the sheep dip, dilute with six parts of water and thoroughly churn or mix before applying the wash to cattle or horses: Cottonseed oil (fish oil may be substituted) one gallon; sulphur, one pound; carbonate of potash, one pound; concentrated lye, three ounces; beeswax, one-half pound; sheep dip, one pint; water, three gallons.

BUYING WINTER VETCH SEED.

I AM so heartily in accord with almost all you say to us in the columns of THE R. N.-Y. that I am glad to have opportunity to take exception now and then. On page 888, in commenting on F. C. D.'s experience with Winter vetch, under the caption "Fraud in Vetch Seed," your last word is "The sure thing about vetch is to raise your own seed." Right here I wish to take exception to that statement, and offer something that may be of benefit to R. N.-Y. readers, and this from my own experience and observation.

For over 10 years now we have used vetches for cover crop purposes, and for the past three years for forage purposes as well. For southwestern Michigan we can find no crop that does as well for cover crop purposes so generally as does the vetch crop. In seeking a source of good seed for this crop we were led into buying seed for friends and neighbors, and have handled as high as 30,000 pounds of seed in a season.

Now as to the comparative merits of imported and home-grown seed: I know nothing of the kind of Winter vetch seed that can be grown in the East. I have never seen a sample of Michigan-grown seed that I would change for a good sample of imported seed. Home-grown seed is always undersized, usually containing a very large percentage of shrunken seeds as well. Several times we have tried home-grown seed alongside of the imported seed. Each time better results have followed the use of the imported seed. Here in Michigan our season is not right for maturing the seed of the vetch. We have had entire crops promise well without producing a single seed. It stands to reason that a seed below the normal size of that seed, if used continuously, will cause that crop to deteriorate.

Our experience with Winter vetch leads us to recommend its use with other plants rather than alone. As a Fall and Winter cover it is not as useful as some other plants. For producing a large, quick growth of highly nitrogenous green manure and quickly decomposing organic matter early in the season, we have yet to find its equal for Western Michigan. A bushel of oats or barley used with 20 to 25 pounds of Winter vetch seed per acre makes as nearly an ideal combination cover and green manuring crop as we have been able to find. If we wish to use the vetches for hay we add one-half bushel of rye or three-quarters of a bushel of wheat per acre. CHAS. H. HILTON.

CLEANING UP FIELD STONES.

A Systematic Campaign Against A Nuisance.

WORKING TOOLS.—How to get rid of surplus field stones with the least labor is a problem of vital interest to many eastern farmers. While clearing up a stony farm we have tried out many ways of handling the work. At one time we built a special tool for gathering up small stones. It was, in effect, an "A" drag, with the wide opening ahead (Fig. 420). The stones and clods are left in windrows about seven feet apart. When hauling away the windrows the wagons can be loaded from both sides. A few years ago we cleared an excessively stony field of seven acres at a cost of $35 for the time of the men employed. As made by us the tool was not entirely satisfactory; but the idea seems so well worth developing that we give full details. We found a 3½-inch clear space between teeth was too wide, and halving it by inserting more teeth made the teeth too close. A clear space of 2½ inches would be about right. The teeth should be heavy enough to be rigid. We used half-inch steel rods and had so much trouble with the teeth bending that we finally abandoned the use of the tool. The teeth should have a length of eight inches in the clear. We found trouble in adjusting the hitching to conform to varying conditions of soil, the drag tilting forward or backward too much. We believe that a drag made along the lines indicated and provided with wheels at the corners would be a good practical tool for clearing ground of small stones, provided the soil can be first put in good condition. It would be pretty expensive on lumpy ground.

THE LITTLE HOG FEEDER. FIG. 422.

GATHERING AND LOADING.—We find that a wagon box that dumps the load by pulling a lever saves much time in disposing of stone. To get the full benefit of the dump box we drive *over* the stone pile. Throwing the large stones to one side and occasionally adding loads of small stones and clods that have been raked up enables us to keep the drive over the pile passable. We have added to this pile until it is now several rods in diameter, seven to eight feet high, and contains over one thousand yards. Mechanical stone pickers have been patented and advertised. A few years ago we made diligent but unsuccessful search for such a machine. We hope that some inventive genius will yet devise a practical apparatus for gathering up loose stones and conveying them into a dump wagon. Such a machine would make farm life seem better worth the living to many a country boy. Getting scattering field stones into a wagon is an irksome and apparently a never-ending task. A coke fork is a convenient tool for handling small stones. The teeth are stiffer than those of a dung fork and the spaces between the teeth are about an inch and one-quarter.

DISPOSING OF THE STONES.—We like to use the surplus stone for building roadways and filling ditches; but when it comes to getting rid of old walls a faster method is called for. With plow and scraper we dig a "canal" as close to the wall as possible, so that the stone can be thrown in without rehandling. The most economical time to do this work is just before Winter closes in. During the slack time with our work, in midsummer, the subsoil is so hard that the cost of excavating is increased. When excavating long trenches it is well to make "sidings" at frequent intervals, to avoid moving the dirt too far. Where a wide trench was undesirable we have kept to the width of the ordinary bail scraper by using either one horse, or two horses driven tandem, for the plowing and scraping.

STONE DRAINAGE.—In one field we struck quicksand and excavated a "canal" that held the boulders from the base of a long line of stone wall. This has given good drainage to a corner that we had been unable to drain satisfactorily with tile. The overflow to this trench is necessarily very shallow, and we were in doubt as to the outcome. Since the first Spring, however, there has been no trouble, the water never standing at the level of the overflow as we feared it might. In the case of a few depressions that cannot be drained at a reasonable cost we are thinking of blowing out large holes with dynamite and filling the holes from nearby walls. To be effective we think heavy charges would be needed, so that we could get down about eight feet into the ground.

THE STONE NUISANCE.—Nothing about a farm is more discouraging than going over the same ground year after year, picking stones. They *seem* never to grow less, and many people believe that such is really the case. The old walls on this farm are, or were, a refutation of that idea. If the entire farm were hand raked to the depth of the furrow we could not get stone enough to replace the old stone walls. One thorough clearing of the seven-acre field above mentioned took it permanently out of the "excessively stony" class. Hand raking the same seedbed year after year, we now have less than one-tenth of the material to haul away that we had the first year. So we may say that the work of picking stone is tedious and expensive, but not altogether in vain. It is an investment that gives a large return in increased crop area, economy of labor and satisfaction at having got rid of the constant annoyance of working the stones over year after year.

PICKING A CROP OF SWEET PEPPERS. FIG. 423.

Monroe Co., N. Y. JAMES VICK'S SONS.

ONE duty of the Kansas County demonstration agent is to keep a list of all persons in that county who have purebred stock or seed for sale.

To show how people watch and read THE R. N.-Y. we may say that recently one woman advised another to make and advertise rompers for children as a means of earning money. Already we have a call from a busy mother who wants to know where these rompers can be bought!

POISONING THE CORN WORM.

A New Method for an Old Trouble.

THE hateful insect that eats into the end of the corn ear has had a sort of monopoly of life thus far. The entomologists had worked out schemes for destroying potato beetles, scale insects or cabbage worms, but it was thought impossible to get at the corn worm with any practical remedy. Recent experiments in New Jersey indicate that this rascal must stand up and take his dose of poison like the rest. The following statement from Prof. C. H. Richardson, Assistant Entomologist of New Jersey, will be good news to many corn growers.

"We found that a mixture of equal proportions of finely pulverized sulphur and dry arsenate of lead, when applied to the growing tip of the corn ear, would kill any of the worms attempting to enter there. As most of the eggs are deposited on the corn silk, the majority of the worms enter the ear at the tip and are thus poisoned. It is important to maintain a coating of the poison on the corn silks during the entire growing season, from the first appearance of the silk until maturity of the ear. The applications of the mixture were made with a small shaker; simply a baking powder can with holes punched in the bottom. A little of the powder was shaken on to the tip of each corn ear as the laborer passed along the row. One application will last about a week under ordinary weather conditions; but if the worms are very abundant should be more frequent, especially when the silk is young."

THE LOCAL STOREKEEPER.

I DO not think much of B. C. Wood's argument on page 830, relative to the local store. One writer, on page 618, states he can see no reason why the country storekeeper cannot sell as cheaply as anyone else. There are others of the same opinion. It is true that the mail order house can carry a much larger stock, but there is nothing to prevent the local merchant having catalogues available from the big supply houses from which he can order goods for his customers, and nine out of ten purchasers would rather let the merchant order goods for him if he could get them anywhere near the mail order prices. Probably the local merchant does not make an excessive profit on his sales, but if he does not buy right he cannot sell right. There is an army of drummers traveling up and down the country selling to merchants, and it costs money to keep them moving, but the mail order houses are not in on this expense. The man who makes his purchases over the country counter helps pay this enormous tax every time he buys anything. Mr. Wood says every country merchant carries his customers and has thousands tied up in accounts, some of which he never gets. The man who pays, however, settles with the merchant for these dead ones. Give the mail order house a five or ten per cent. advantage on this item. The remedy for this lies with merchants and their associations.

Your local bank extends credit, but bankers do business along business lines, and the average sucker doesn't put one over very often on these people, and through them on the man who does pay, by reason of a no-good business system. I believe the public prefers to trade at home, and local merchants should be progressive enough to get in a position to furnish anything the catalogue houses can at prices equally low; then the quarrel will end.

New York. C.

R. N.-Y.—It is understood by all that THE R. N.-Y. attempts to discuss these public matters in a fair and broad way, by giving all sides a fair hearing. It does not follow that because we give a person space to state his views, we fully agree with him. If his position is unsound, fair discussion will prove it so. We ask correspondents to be fair, honest, good-natured—and brief.

GERMAN railroads carry manure and fertilizer at 20 per cent. less than the regular rates. These rates are openly for the encouragement of farming.

Harvesting Sweet Potatoes.

WILL you state how sweet potatoes should be handled after they are taken from the ground to insure their preservation for at least a reasonable time? Is September 10 too early to take them from the ground? F. R. J.

Trenton, N. J.

September 10 is not too early to dig sweet potatoes for storage, but they are usually dug later so that the yield will be larger. Most growers claim that sweets are a trifle more resistant to rots in storage when dug early, and while still immature, than are the fully matured potatoes. In some sections cuttings are made of the ends of the vines in June and the small potatoes, called slip seed, grown from these vine cuttings or slips are very immature when dug but they invariably keep better in storage than the mature potatoes. In order to have sweets keep over Winter they must be free from disease, dug before the ground freezes, handled carefully to avoid bruising and placed in a room where plenty of ventilation can be given. When first stored a temperature of 80 to 90 degrees F. should be maintained, and all possible ventilation given until the potatoes have gone through the sweating stage, after which the temperature can be reduced and held at 45 or 55 degrees F. F. R. J. will find that he can keep sweet potatoes a reasonable length of time in an ordinary living room, provided he keeps them at a high temperature and gives plenty of ventilation for a few days until they have gone through their sweat. After they are once stored sweets should not be disturbed any more than is absolutely necessary.

TRUCKER, JR.

Utilizing the Cull Apples.

I LIVE here in Western Colorado in a mountain valley, elevation 6,200 feet. Our principal product is fruit, especially apples of high quality. The leading apple here is Jonathan, which ripens generally by October 10 and is of high color. But we have one drawback; we have no way to dispose of our culls or inferior apples, and every year a great many go to waste in the valley. The only profit we get is from our fancy box apples, as shipping the culls east the freight is too high and there is too much of the same stuff east, and cheaper, so we cannot compete with them. Another drawback, labor is high, 25 cents an hour is the cheapest you can get anybody. There have been several suggestions made to dispose of these apples here, but none has been tried. We shall have more culls than usual this Fall, as we had a hailstorm here which put them in bad shape. Some say an evaporator would pay well, some say vinegar, and one apple man thought an apple butter factory would pay well. What suggestion could you give? I would like some way of disposing of this waste; it would lighten our expenses on our high grade fruit. H. J. W.

Cedaredge, Colo.

R. N.-Y.—We will turn that over to our readers for discussion. In New York State many would say "evaporated apples" but they might not pay in Colorado.

The Illustrations.

THE two pictures shown at Fig. 422 and 423, page 987, give a wide contrast in methods and ideas of farming. On the Western plains far from the town, the farmer would be foolish to plant a crop of Italian peppers such as is shown at Fig. 423. In Southern New Jersey, however, this crop is frequently a very profitable one. The cultivation is much the same as that for tomatoes. The pepper crop can be picked through a series of weeks. It does not have to be taken off like the tomato, just when it is ripe, and therefore the picking may be extended over quite a long period. Within recent years the demand for peppers has increased remarkably, and when well cultivated on the light soils of Southern New Jersey the crop often gives excellent returns. The fact is that farming has now come to be a business of specialties, and a man who expects to make his living from a piece of land must know what that land is best able to produce and adapt his crop to the soil and also to his markets.

The other picture shows a scene on a hog farm in Western Iowa. The little girl has filled a pail with ear corn, and has gone out to offer some of these ears to the brood sow. This is a cunning picture as it shows the child. We consider it dangerous to put children in such a position, unless there are grown-up people close by. The sow in the picture may be entirely gentle and good-natured, but if she is hungry and takes a notion to get hold of that ear corn in the pail, it would be an easy matter for her to knock down and trample over the child. We never like this idea of putting children on the back of a cow or a bull to ride, or having them go among other live stock carrying food in this manner. No one could trust a hungry brute, and without showing a vicious or ugly disposition they would be quite likely to knock the child down while hunting for the food.

In the Gypsy Moth Country.

I WONDER how many of the R. N.-Y. family have orchards infested with the Gypsy moth? We have been fighting them for several years, but have not been able to exterminate them entirely. We have nearly 100 trees, mostly Baldwin apples, and we let the hens and chickens range in the orchard. We have been teaching the hens and growing stock to eat the Gypsy caterpillar and pupa, also the moth when we can catch it. All this month we are hunting for the caterpillar on the under part of limbs, under loose bank and in any cavity. We throw an old bag, fertilizer bag, over the crotch, or lower limb and trap them the same as burlaping. Every day or two we look under the bags and kill the caterpillar or pupa and the hens and chickens will follow me from tree to tree after them. The trees have never been scraped. I think it would be a benefit, but we never seem to have time to do a thorough good job. I took a scuffle-hoe and put in a long handle and somewhat straightened it. I find it a very handy tool to kill the caterpillars and to scrape off the loose old bark. The caterpillars will hide under the loose bark and go into the pupa stage. This transformation is very rapid and to catch them before they become moths you have to be "Tommy on the job." In the Winter we go over the trees and paint with creosote the Gypsy nest, but however carefully we look, some will get missed. In our spraying we use six pounds arsenate of lead to 50 gallons water, but still we have a good many left to fight. What with these and the Brown-tail moth, to say nothing of the germs and other fungus, that make war upon our fruit trees, it does seem as if about all a man's time is taken up, if he really expects to get any fruit worth while. M. T. W.

Massachusetts.

Spring vs. Fall Seeding.

MY reasons for Spring seeding are these: First, I am sure of a good catch by seeding grass with grain. Most of my land is clay and muck, and it is impossible to get seed in early enough for grass to get start enough so it will not heave out, as the land heaves badly in the Spring. Plowing has to be put off five seasons out of six until well into September, in order to have the soil moist enough. I have tried Fall seeding, but it is always a total failure. M. B.

Lewiston, Me.

Inoculated Peas.

LAST year I purchased some commercial bacteria from a seedsman and inoculated peas before planting. Those inoculated produced at least a third more peas and of better quality than a row that was not inoculated. This year I purchased another kind from another seedsman, but was unable to see any benefit from it. Can you tell me anything about the different brands of inoculation? A. S. A.

Alstead, N. H.

While we think some brands of these inoculating bacteria are more reliable than others, the incident you relate would not be definite proof. All these "inoculators" can be expected to do is to add the bacteria needed to enable the plant to take nitrogen from the air. In the first case there may not have been any of these bacteria on the peas or in the soil. Therefore the inoculated peas made better plants. In the last experiment the bacteria may have been in the soil. Then introduction through the commercial product was therefore not needed and there was no reason why these peas should do better than the others. This is just the thing we should keep in mind when figuring on these commercial bacteria. If the bacteria are already in the soil we do not need to buy them.

Fodder Corn.

I AM an amateur woman farmer, and have about one acre of meadow that has been used as a yard for cattle. Could it be plowed now and planted with any crop that would help feed young stock during the Winter? Of course it would need little fertilizing as 20 yearlings were on it most of the Fall and Spring, also during Winter were put there pleasant days. Is it too late to plant corn? If not tell me just how to treat it, as hay is scarce here this Summer. M. S.

New York.

Our plan would be to plow that sod at once, fit it properly and sow fodder corn. This means making furrows about three feet apart and sowing ordinary field corn thickly—about two bushels per acre. Cover lightly and give good culture. The corn will not mature grain, but it will give a large quantity of fine tender stalks, which when cured will make a good substitute for hay.

Recent Experiment Station Bulletins.

"BACILLARY White Diarrhœc," in young chicks is discussed in a fourth report upon this subject from the Experiment Station at Storrs, Conn. In Bulletin 77 the carrier problem, a test for determining the presence of infection in grown fowls and the effect of sour milk feeding upon growth and mortality of young chicks are treated at length.

"Constitutional Vigor in Poultry," is the subject of Bulletin 345 from the College of Agriculture at Ithaca, N. Y. The results of their further study of this subject confirm previous conclusions and show that selection of fowls for strong vitality increases the productive power of a flock.

The detection of infection with white diarrhœa through examination of the eggs laid is discussed in Bulletin 148 from the Massachusetts Experiment Station at Amherst. Owing to the irregularity of the appearance of the germs of this disease in eggs from infected fowls, the conclusion is reached that it is not practicable to detect diseased hens in this way.

"Beef Scrap and Cotton Seed Meal," as sources of protein in the ration of growing chicks are compared in Bulletin 156 from the R. I. State College at Kingston. It was found in a series of experiments that cotton-seed meal had no apparent deleterious effect when fed to chicks, and might be made to furnish part of the protein required. If the most rapid growth was desired, however, the beef scrap ration was found to be the most satisfactory.

"The Composition of Corn," at various stages of its growth, is given in Bulletin 175 from Purdue Experiment Station at Lafayette, Ind. A handsome colored chart accompanying this bulletin shows the amount of plant food in one acre of corn at five different stages of its growth.

"Experimental Work in Connection With Cranberries," is reported in Bulletin 150 from the Experiment Station at Amherst, Mass. This bulletin will interest cranberry growers.

"Classification of the Garden Varieties of the Sweet Pea," will interest professional growers and many amateurs. It is Bulletin 342 from the College of Agriculture at Ithaca, N. Y. This bulletin states that there are now almost a thousand variety names of sweet peas. M. B. D.

ILL-SMELLING WATER.

WE have a well in front of our house that was always good until a month ago, when we noticed there was an odor to the water On opening it we found that some surface water had found its way into the well. We cleaned it all out and then cemented the wall down about four feet from top. The water is clean now, but still has the odor.
New York. J. W. M.

It may be that this well is being polluted by underground drainage from some cesspool, privy vault, or other source, or it may be that the surface water still finds its way down the well curbing to enter beneath the cemented portion of the curb. Without an examination of the premises it would be impossible for anyone to say definitely what the cause of the bad odor is, but, if the well is known to be clean, the source of the trouble should be looked for in possible entrance of surface water or in the proximity of some cesspool, privy vault, barnyard or other evident means of possible pollution. If the soil is of sandy or gravelly nature, it is probably for a cesspool 200 feet away to contaminate it, while if it is in a limestone formation, it may receive the contents of a cesspool or vault situated many times that distance from it.
M. B. D.

DOUBLE CROPPING VEGETABLES.

AS regards inter-cropping in Eastern Massachusetts, as the rule this is not practiced by the leading growers, as many of these believe the gain from the profit of the two crops will not make up for the loss the second crop will cause or take away from the first; in other words the crop grown alone needs all the benefit of the land and contents, and will respond to the same and use it so the result will be a larger crop both in bulk and character and also a more satisfactory crop of size and quick growth which insures tenderness, a very essential quality in many market crops, in fact nearly all. Many who formerly grew two crops on one piece of land now grow only one, and get more cash returns from this per acre than when two crops were grown, one perhaps at a loss, for many reasons. Condition of market at time crop was ready might be one, destruction by frost another, and so on. Take the squash crop for example. Formerly this was grown between some other and started between some other, and is yet in a few cases, but it has been found by our best growers that even this crop does better, gives larger returns per acre in actual cash, by planting alone and not crowding the hills too close, giving it the whole benefit of land it occupies and the season we have properly to mature it.

There are, of course, successful cases of growing two and even three crops on some of our farms. The Hitenger fruit farm of Belmont is the best example I could give of this, where practically every inch of the ground is occupied by a growing crop, and a large number of hired help used all the year to care for and harvest these, and a large and profitable income is secured. Very heavy manuring must be done in these cases, and a large supply a few miles away makes this possible. Were it not so handy this system would be impossible to carry out successfully and make it pay.

Spinach is a very important crop to Boston market growers, and is about the leading one. It requires heavy manuring, grows very quickly, requires little attention when growing, and is easily got ready for market. The price is many times very low, sometimes only 10 and 15 cents per bushel, at others perhaps 50 or 75 cents, and when the lucky grower gets this for a good share of his crop he is well satisfied, and ought to be. This crop is planted both in Spring and Fall, carried over Winter, and early in the Spring is ready to cut and sell in time to plow the land, get in another crop of almost any kind, and mature the same season and repeat the process over again. This crop is planted at all seasons of the year, but largely as I have stated, or early in the Spring, and in this case is soon ready to sell and another crop put on the ground. Lettuce is another Spring crop which can be followed by the second crop the same season.

Celery is the leading second crop, and is often set and started before the preceding crop is off the field. This crop requires much attention, and must be kept growing all the time. It returns usually a very satisfactory profit per acre to the grower.

Tomatoes are sometimes set between the rows of some early crop like peas or beans, and also a few other crops, but the practice is largely to grow them alone, as cultivation can be given easier, and really better results be obtained. It is possible to grow spinach, lettuce and celery on the same land in one season, and get good results, and this is done in a few cases. A few growers plant spinach, radish and lettuce between nearly all crops they grow, and get good results. The Cooledge farm on the edge of Cambridge does this to a large extent. Their location being only an hour's haul from the market, and their manure supply being about the same distance, is a large factor in their favor, as several loads per day can be placed on the market when necessity or demand requires it, and this is a great advantage; in fact, many times makes all the difference between a season's success or loss.

Formerly string and shell beans were largely grown between sweet corn. They are yet to some extent, but better results are obtained by separate planting. Nearly all crops need much sunlight, and if one shades the other more or less loss is the result. This may occur in many forms, growth, color or something else, and a spindling plant of any kind is not what we want.

Turnips and cabbage can be grown after spinach, lettuce, peas, beans and other early crops. The question of fertility of land is looked after in this way by most growers. They dress the land heavily with manure at each cropping if possible, using manure that has been piled and seasoned for some weeks if available. Very little fresh manure is used except that from hogpens, which is applied direct on most crops, but not all. Fresh horse manure as it comes from the stables is largely straw, and not fit to use to obtain quick results, so it is piled in heaps and let heat and rot until in suitable shape to apply. Of course much nitrogen is lost in this process, but gain in other forms may perhaps balance this.

To carry on the systems of inter-cropping successfully plenty of help must be had at just the right time; a day or two's delay means to lose a crop in many cases, as many of these crops will only grow when conditions are just right, and in order to get two and three crops in one season, everything must be done on time, no matter what the cost. No crop can be allowed to lag any more than the teams or men can. Everything must be kept moving every minute to insure success.
Massachusetts. A. E. P.

CROP REPORTS.

July 16. Old hay $14; buckwheat $1.80 per hundred; old potatoes 50 cents. Frosts injured peach crop, light production; wheat and oats good, apples fair.
Southern Cayuga Co., N. Y. J. W. P.

Hay quality fine and extra big crop. Corn, beans and potatoes late, but looking well, and growing fast, so have hope of an average crop. Old potatoes bringing $1.25 per bushel. Apples are looking well and prospects for an average crop. M. B.
Maine.

July 19. Hay $20 per ton (old hay); Holstein cows of good size that have dropped calf within one month, from $75 to $100; butter 28; eggs 30. Cream 30 cents per quart; milk five cents per quart. Potatoes are selling for 45 cents per peck or 60 cents per half bushel (these are new potatoes). E. K.
Ulster Co., N. Y.

July 13. Our milk the past week brought from the cheese factory $1.21 per 100 pounds for 13¾ cents cheese; the week before $1.28. I understand the milk stations are paying $1.10. Milch cows $50 to $100; bulls $5 per cwt.; yearling heifers $30 to $35; veal calves 10 cents per pound. J. S. M.
Edwardsville, N. Y.

July 20. Butterfat from 22 to 25; eggs 20; wheat, old, 85 (new will start at about 70); oats 45; more oats are bought than raised here. Corn 70; rye 75; hay $12 to $15. Cattle five cents to 7½; hogs, dressed, nine; milch cows, around $70 for good ones. Horses high, mostly shipped in; fairly good work horses at $450 to $500 per pair. Not nearly enough hay raised in this section to supply the need. More and more Alfalfa is being sown each year. It does better than other clover as our soil is open and naturally drained, the water table being down about 60 feet. We are too far from the lake for fruit to do its best, and orchards are small yet. Staples here are potatoes, beans, buckwheat, and corn. All these crops are looking exceptionally good. R. H. U.
Mancelona, Mich.

July 17. Hay $22, in small lot; straw $15; oats 60. Butter 35; milk seven to 10, certified 15; cream 50 per quart. Potatoes $1; eggs 30. Our place is not much of a farming district. We raise no fruit, only a very little corn. It is strictly a Summer resort. We have from 2,000 to 2,500 city people with us from June 1 to October 1, about the same number each year. No doubt this keeps prices rather high. W. E. T.
Lake Placid, N. Y.

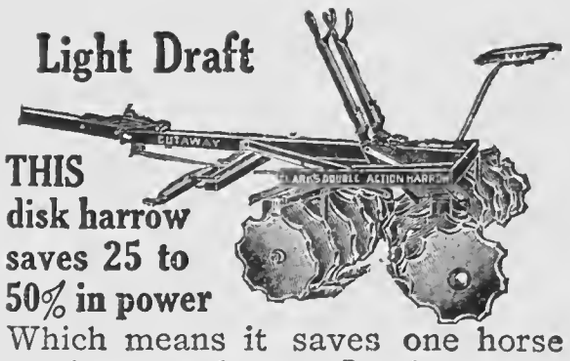
July 15. There is not much dairying or gardening done here. The leading crops are corn, wheat, oats and some live stock, horses, cattle, sheep and hogs. Nearly all grain (except wheat) and all hay is fed on our farms. Prices of horses $150 to $250; cows $50 to $80; fat steers seven to nine cents per pound; hogs eight to 8½; butter 25; potatoes $1.25; cabbage 2½ cents per pound retail, $1.75 per cwt. New wheat 76; oats 50; corn 77. R. W. M.
Fannettsburg, Pa.

July 13. Hot and dry, corn and gardens needing rain badly. Wheat mostly hauled; grass more than half cut. Plenty of fruit, early apples beginning to ripen. Oats about ready to harvest. Horses not selling quite so high as one year ago; all other live stock a little higher. Wool all sold at 25 and 28, mostly sacked and shipped. Early potatoes will be a short crop. Not much live stock selling this time of year. Corn 90; wheat 90; oats 50; butter 20; eggs 18; chickens, young, 20; old 12. W. B. H.
Morgan Co., Ohio.

July 20. The farmers are just beginning to cut their hay; the crop is light, for though near a lime center, hardly any use lime, even though it is on most fields, badly needed. Native strawberries have been in the market about two weeks, prices holding good, retailing for 15 cents. Blueberries ripening well and very plentiful, selling now in the stores for 15 cents a quart box. A little later they will be sold to the factory in larger lots, or shipped to Boston in crates. The gardens are doing well, for there has been no drought here this season, but hardly anyone has cow beets, for just as soon as they showed above the ground powder-bugs ate and killed them. Corn, and its prodnets retail for $1.70 per cwt.; bran and most mill feeds, $1.60 per cwt. Oats are 58 a bushel; wheat $2 per cwt. Old hay $10 to $14 per ton. J. C. S.
South Thomaston, Me.

Fruit prospects in Crawford County, Penna., are poor; few apples, part of a plum crop, and there will be no peaches. Hay will be 65 per cent. of crop with but little left over. Oats are short because of earlier need of rain. In many sections of the county wheat is considered better than any previous year in a score of years. No cows are being brought from the adjoining dairy section in Ohio owing to the necessity of testing cows brought into the State for tuberculosis. Formerly two-thirds of the cattle purchased in the western part of Crawford county, came from Ohio dairy farms. The State law requires 3.7% test, and for this test during the Summer the Rick factory, near Conneautville, is paying $1.30 per hundred, and deducting three cents a hundred for each one-tenth per cent. below the legal test. During Winter months this factory paid $1.80 a hundred and in April $1.60. Many farmers from the county shipped milk to Pittsburg during the Winter and Spring. They received $2 a hundred for Winter milk and $1.50 for Summer milk, net. Many of these shippers in the county and adjoining territory have been cut off owing to oversupply, and a shortage in demand owing to many people being unemployed and unable to buy milk. The amount of milk produced is the same as last year; and the Rick factory is installing a condensery plant to handle its surplus product. Good cows are selling from $75 to $125 and poor cows from $30 to $60. There is a live demand for purebred stock in the county. Butter has been selling at 20 and 22 cents at local store, and eggs 17 cents. Poultry breeders state this is a poor season for hatching. N. J.
Crawford Co., Pa.

Light Draft



THIS disk harrow saves 25 to 50% in power

Which means it saves one horse at the very least. It also saves one man. And, furthermore, this

Cutaway (CLARK)

Double Action Disk Harrow

pulverizes the soil finer than any single harrow working in "half-lap." And more—it pulverizes finer than any two single harrows attached in tandem. Its rigid main frame holds the rear disks so that they cut just midway between where the fore disks cut. All soil is pulverized to the full depth to which the disks are run. Ask your dealer to show you a CUTAWAY (CLARK) Double Action. If he doesn't sell CUTAWAY (CLARK) harrows, write us. Don't accept a substitute. We ship direct where we have no agent. Ask for free catalog, "*The Soil and Intensive Tillage.*"

EVENTS OF THE WEEK.

DOMESTIC.—One man was killed and several injured in an explosion at Jasonville, Ind., July 24, when dynamite was used in an effort to check flames that threatened to sweep the entire business section of this city. The damage is estimated at $400,000. Jasonville was practically without water supply because of the drought.

Three persons were killed in a terrific windstorm that swept down on Joliet, Ill., July 24. Seven persons were injured.

With dynamite and power drills nearly a thousand men, working in relays, saved the lives, July 28, of fifty workmen who were imprisoned by a cavein 4,500 feet from the east entrance to the St. Paul Railway's 12,000 foot tunnel under the Cascades at Snoqualmie Pass, Wash. The cavein cut off the power for the drills, leaving the crew helpless. Between the imprisoned men and the 7,500 foot bore at the eastern portal was a hundred and fifty foot rock barrier. All the crews at the western portal were put to work on double time in swift relays. For twelve hours they worked as fast as human endurance would permit, piercing the barrier four days ahead of the time set by the engineers. The imprisoned were rescued without injury.

Charges that government witnesses had been tampered with and important evidence had been destroyed were made in the Federal District Court at New York, July 28, against the Franklin Candy Company, Inc., the principal officers of which are on trial charged with using the mails to defraud investors. Kenneth M. Spence, Assistant United States Attorney, asserted that important cash books, ledgers and letters which were found by the government when the company's offices were raided a year ago were permitted to be taken away by John F. B. Atkins, who appeared for the defence. Mr. Atkins was called to the stand and was unable to tell what had become of the books and papers. The defence finally agreed to let the government introduce as evidence its statement made up from the missing documents before they disappeared.

The boldest holdup in the history of the West took place July 29, when two masked bandits held up 45 stage coaches in Yellowstone Park and robbed the 165 passengers of more than $4,000. The robbery occurred at Shoshone Point, which is on top of Continental Divide and midway between Old Faithful Geyser and the Thum lunch station.

Fire in the Morris lard factory, in the Chicago stock yards, July 25, destroyed the carcasses of 5,000 hogs, many tons of lard and other property; loss estimated at $500,000.

The factory of E. S. Parkhurst & Co., manufacturers of hair and woolen goods, Gloversville, N. Y., was destroyed by fire July 26, with a loss estimated at $300,000. No water was available, as the plant was outside the city.

Two persons were drowned, 50 families were rendered homeless and 15 business blocks, including one hundred buildings, were partially wrecked at Telluride, Col., July 27, when a wall of water ten feet high, originating in a cloudburst, decended through Cornet Canyon, broke through the dam and flooded the town. The damage is estimated at $150,000.

FARM AND GARDEN.—H. O. Havemeyer, whose estate at Mahwah, in the valley of the Ramapo Mountains, New Jersey, comprises about one-half of Hohokus Township, has sent a bill to the Hohokus Township committee for $769, representing the value placed upon five blue ducks, worth $75 each; two dozen pheasants, valued at $6 each, and half a dozen geese, worth $25 each. These fowl were killed by wild dogs, a number of which are said to infest the Ramapo Mountains. Mr. Havemeyer's lawyer holds that the township committee is responsible for permitting the dogs to run at large. The township committee realizes that $769 is a lot of money for dead ducks, pheasants and geese, so the bill was sent to the State Fish and Game Commission at Trenton.

The Farmers' Union of New Zealand passed a resolution, July 24, urging the government to watch the operations of the American meat combine and prevent it gaining the foothold in New Zealand it already has gained in Australia.

Considerable interest is being shown by farmers in a proposed visit to the farms of Middlesex, Mercer and Monmouth Counties, N. J., by a number of famous German plant pathologists, together with leading plant disease men of the Department of Agriculture at Washington. Although the time of the visit has not yet been definitely decided upon, it will probably be made during the early part of August. Included among the government officials who will be members of the party, will be Dr. W. A. Orten and Prof. William Stewart, both of whom are connected with the United States Department of Agriculture. The tour will be under the direction of Dr. Melvin T. Cook, plant pathologist of the New Jersey State Experiment Station at New Brunswick.

The new regulations governing the shipment of potatoes from Maine, which the presence of powdery scab in that State has necessitated, have now been promulgated by the U. S. Department of Agriculture and took effect on August 1. These regulations supersede the inspection hitherto carried on by the State authorities and are primarily designed to prevent the spread of powdery scab to other sections of the country. With this end in view the inspection is made especially strict for all seed stock. This must be grown from clean seed and in soil not infected with powdery scab, and have been free from contact with anything through which they might have become infected with the disease.

The schedule of premiums and awards for the Maryland Week exhibition, to be held under the auspices of the Maryland State Horticultural Society, Maryland Crop Improvement Ass'n., and the Beekeepers' and Dairymen's Ass'ns., has been published. The exhibition will be held Nov. 16-21 at the Fifth Regiment Armory, Baltimore. Copies of this may be obtained from T. B. Symons, College Pk., Md., secretary of the Maryland State Horticultural Society.

Health Commissioner Goldwater of this city wants more stringent ordinances for the control of dogs, owing to the spread of rabies. More than 40 cases of rabies have developed in Bronx borough since January 1, against nine in the same period in 1913. In all the other boroughs, except Brooklyn, there has been a rapid spread of the disease. The first five months of this year showed 73 cases in Manhattan, against 110 cases for all of 1913. Queens had 38 cases in 1913; this year the borough has already shown 27 cases. Richmond has already had two cases; last year there were four in all. In Brooklyn there have been only 19 cases thus far, against 71 for 1913. Only one person has died so far this year from the disease, against eight in 1913, six in 1912, and some very high records in other years, notably in 1908, when the high mortality of 28 deaths from rabies was recorded.

THE EUROPEAN WAR.—July 30 the dual Empire of Austria-Hungary declared war against Servia, and immediate invasion began, with the bombardment of Belgrade, the Servian capital. Great Britain had urged arbitration, but the influence of Germany was on the side of war. Great tension exists between Germany and Russia, and both countries are mobilizing their forces. Russia will not permit Servia to lose her identity. Both France and England are working for peace, their interests being thrown on the side of Russia. Italy, while neutral, is inimical to Austria, and an ally of Great Britain, Greece is believed to be ready to aid Servia. While all European nations are preparing for general war, the outcome was in doubt July 31. All of the Balkan States, Servia, Bosnia, Bulgaria, Albania, Herzegovina and Montenegro, were expected to unite against their common foe, and in this they would be backed by Russia.

OREGON NOTES.

MY experience with the Marshall strawberry is like the Hope Farm man's. July 20 I picked a pint of lovely big berries and they have been bearing since May 21. Everything was very early this year. A thrasher is setting up this morning in our vicinity. Usually this goes over until the end of August. Fourth of July people were saying the cherries were about gone. Everyone is in the milk business. Cows with first calf, or rather heifers, for they are barely two years old, bring $100. We were asked $125 for grade Durhams a few weeks ago, and they appeared to be only scrubs. The high prices that were put on lands are all gone. So many easterners went back to where they came from. Potatoes, new, are selling at $1.25 a sack; apples $1 a box and are over supply. There is a cabbage famine. Local peaches arrived last week and California stock is from 50 to 90 cents a box. There is a public market in Portland. A charge of 10 cents a day is made for stalls. One can buy anything in any quantity; it is in the down town district. Local corn was selling July 17 at 60 cents per dozen. C. J. H.

Beaverton, Ore.

FRUIT PROSPECTS IN NORTH CAROLINA

THOUGH early Spring prospects were very favorable for a bumper crop of nearly all kinds of fruits, the long-extended drought lengthened the season of the "June drop" and thereby subtracted proportionately from the final total. Orchards on which cultivation was started early and persistently followed through the dry spell suffered very little from the drop. There was however one advantage about the dry spell, if it was bad for fruit it was also bad for insects and especially fungus diseases. Early peaches showed practically no brown rot even when unsprayed. Apples, though a little small in size, are clean and free from scab and blotch. Bitter rot could scarcely survive the hot parching days. Blight seems to have been worse than usual this season on pears and especially so on apples. In the last week or so the drought has been broken in all parts of the State and all late fruits are coming on in fine shape. The averaging up of a large number of reports from growers gives the following percentages of crop: Apples 65% of a full crop; pears 55%; peaches 65%; grapes 92%.

W. N. HUTT,
State Horticulturist.

July 21. Crop conditions very favorable at present; good soaking rains on the 14th and 15th, which seemed to bring new life to the growing crops. Weather had been dry and hot for the past few weeks, and the rains were very much appreciated by the farmers. Wheat thrashing about done and crop unusually good. Oat crop not very good. Plenty of apples and peaches now ripe. Green bean scarce on the account of no rain. Corn $1.05; wheat 90; oats 50; potatoes $2; hens 10; Spring chickens 12½; eggs 13; butter 15. Good horses and good milch cows very high; hogs 7 to 8; stock cattle 5 to 8. W. H.

Washburn, Tenn.

July 21. Wheat 62; oats 36; wheat and oats fair crop. Corn 75, new crop drying up on account of drought. Potatoes $1 a bushel; Winter supply is shipped in from Colorado. No fruit and very little garden stuff, too dry. Hogs $8.40 to $8.50 a hundred; fat cows $5.50 a hundred to butcher. Cream 18 cents a pound, butterfat; butter 15; eggs 10.

Apache, Okla. E. H. G.

July 24. We are having an extremely bad drought in this section and all kinds of feed promise to be very high this coming Winter, particularly hay and other roughage. The drought is general but is worse locally than elsewhere. Corn is burned up, cotton must have rain pretty soon or there will be no crop, the second cutting of Alfalfa was either absent or very short. Eggs 12 cents per dozen; butter 20 to 22; hay, wild prairie, $10 per ton; hay, Alfalfa, $12; cows, dairy, $50 to $85, rather scarce. Horses, good work type, $100 to $150, rather slow sale at this season. Chickens, hens, 10 cents per pound; Springs, 12. Corn 80 cents per bushel; Kafir corn 75; oats 30; wheat 65. N. O. B.

Stillwater, Okla.

July 23. Conditions in this part of Nebraska are very good at this time. A large acreage of Winter wheat has been harvested, thrashed and a good share of it sold and shipped away. The crop is somewhat disappointing in yield, the average being about 20 bushels per acre. The slump in yield was probably due to Hessian fly, the damage done by the fly being more than was expected. Oats are very good, and the yield from 60 bushels per acre down. The weather has been ideal during cutting and thrashing, and the entire crop has been thrashed from the shock without being wet. Corn is now in tassel and silk, and is looking extra well, but is in need of rain. No rain has fallen in three weeks. Two good cuttings of Alfalfa have been harvested, but the third is a failure, and will barely pay for the cutting; which must be done. Whether we are to have a crop of corn or not depends on the coming of rain within a week or two. Trade seems to be fairly active and more farmers have bought automobiles this season than ever before. Prices for cows have been reduced somewhat, because of the low price of butter and butterfat. Good cows $60 down; hogs $8 per hundred; butcher cattle 6 to 7 cents. Spring chickens 18; hens 10; butter 17; eggs 16; butterfat 20 for sour and 30 for sweet. H. M. R.

Fairbury, Nebr.

COMING FARMERS' MEETINGS.

Thirty-ninth Annual Convention of the American Poultry Association, to be held at Chicago, Ill., August 8th to 15th, 1914, inclusive.

Northern Nut Growers' Association, annual convention, Evansville, Ind., August 20-21.

National Dairy Show, Chicago, Ill., October 22-31. The following meetings and conventions will be held in connection with the show: American Association Creamery Butter Manufacturers, Oct. 26. Holstein-Friesian Association of America, Oct. 26. International Milk Dealers' Association, Oct. 26 and 27. Conference, Secretaries of State Dairymen's Association, Oct. 27. Official Dairy Instructors' Association, Oct. 27. National Dairy Union, Oct. 28. American Dairy Farmers' Association, Oct. 28. Council of the National Dairy Show, Oct. 28. National Association of Creamery Managers and Owners, Oct. 28. American Jersey Cattle Club, Oct. 28. National Association of Ice Cream Manufacturers, Oct. 28, 29 and 30. International Association of Dairy and Milk Inspectors, Oct. 29. American Guernsey Cattle Club, Oct. 29. Congress of Marketing, Oct. 29. Milk Producers' Association, Oct. 30.

Maryland Week Exhibition, State Horticultural Society, Maryland Crop Improvement, Dairymen's and Beekeepers' Associations, Baltimore, November 16-21.

Annual Show of the Paterson, N. J., Poultry, Pigeon and Pet Stock Association, November 18-21.

Indiana Apple Show, Tomlinson Hall, Indianapolis, Ind., November 18-24.

2000 Farmers in Arkansas

have been supplied by the State with

Ferguson's NITROGEN BACTERIA

This is in connection with a concerted movement to advance the growing of Alfalfa in Arkansas. Realizing the great possibilities in this crop when given thoroughly favorable conditions, the State has supplied 2000 farmers with a quantity of seed, lime and Ferguson's Bacteria for Nitrogen Inoculation.

Ferguson's Bacteria are a composite culture, for all legumes—Alfalfa, clover, vetch, peas, beans, etc. They gather Nitrogen from the air and store it up as plant-food on the roots of the plants. A large part of the Nitrogen is left in the ground to enrich it for the future.

Costs only a fraction as much as the best commercial fertilizer

Quarter-acre quantity, 50c.; 1 acre, $2; 5 acres, $9. Let us explain why you need Nitrogen Bacteria and why Ferguson's is best. Write for special booklet N—free.

Farm Engineering.

Locating a Well.

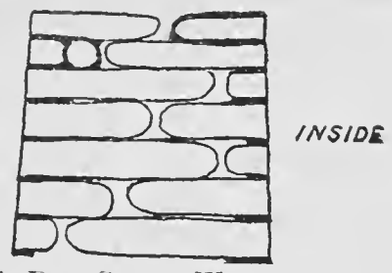
IT may be hard for some of us to believe it, but the geologists have the upper crust of this old earth well mapped out, both as to minerals and water. Most men seem to believe that all they need do is to dig a hole in the earth and take the water out.

The geologists and engineers of the Geologieal Survey know of many wells that have been drilled from 600 to 2,000 feet in depth in places where an expert eould have foretold with eertainty that little or no water would result. Not infrequently people write to the Survey that they have spent hundreds or perhaps thousands of dollars in drilling to great depths and inquire whether they shall go deeper. An examination of the geologic maps or data at hand has more than once brought the reply that the formation being drilled was not water-bearing.

Some "water witch" will probably elaim that he can beat the geologists in locating water; but at any rate some soils and locations are better supplied than others and it is worth money for us to know about it before we start.

Keeping Stone Wall Dry.

ON page 924, C. P. asks how to protect wall from damp. Fifteen years ago I put a basement under my barn, built of field stone mueh like the drawing shown, taking pains first that no stone went elear through the wall from outside to inside, and seeond, taking pains that the stones lapped onto each other, this for strength to bind the wall together. Third, I only put the mortar about three to five inches in from the outdoor side of the wall, and also from the indoors side of the wall, leaving the inside or center of the wall without mortar



A DRY STONE WALL.

for six to 10 inches. When the wall is properly pointed it will be warm as regards wind coming through. If the stones lap properly it will be strong if it has a proper foundation, and if no stones go clear through you will find no frost to speak of on the inside of wall; at least that has been my experience, but in one plaee in my basement a large round stone goes clear through, and that is always covered with frost in cold weather.

The cellar wall to my house on the east side bothered me by getting frosty on the inside in spite of a dirt banking. I wished to build a piazza on that side, and knew a dirt banking would be almost impossible to keep in order, and I tried the experiment of building a wall outside the cellar wall. Before the piazza was built I mortared the outside and top of the new wall but did not put any mortar between the two walls, thus leaving a dead air space between the two walls. It was a success; that dead air spaee did the trick. F. L. B.

Hamilton, N. Y.

Lifting Water With Siphon.

I AM digging a well and wish to ask some questions coneerning it. How high would a siphon lift water from a well? The distance from the buildings is about 550 feet; the level from top of the well is about 65 feet. B. F. L.

West Leesport, Pa.

A siphon, if every condition is perfect, will lift water about 34 feet over an obstruction or hill to a lower level on the other side. That is, it will not raise water to a tank or something of that kind, but, rather, the delivery pipe must be below the souree of the water. If a spring is on one side of a hill and you want water in a valley on the other side, a siphon will raise the water over the hill and down into the valley without pumping. It will lift water out of a well, over the curb and down to buildings at a lower level. This appears to be your case. Praetically, the surface of the water must not be more than about 32 feet below the eurb. Then, all that is necessary is to run a pipe from below the surface of the water in well to the buildings and fill the pipe full of water to exclude the air. Then open up your faueet and the water will flow. The pipe must be kept full of water. If it is airtight, it will remain so of its own accord. To fill the pipes at first, a suction pump at the faucet or a force pump at the well will do the work. If these cannot be obtained, you can pour enough water in to fill the pipes by stopping up the well end and opening up a joint at the well eurb, putting in a tee and raising a standpipe up a foot or so. In this standpipe plaee a valve. Open the valve, fill the pipes, close the valve, open a faucet at the buildings, and then open the well end of the pipe line without lifting it above the water surface. Be eareful, after filling the pipes with water, to allow no air to enter the pipes. A big siphon like this aets just the same as a small siphon made of rubber hose and used to empty a pail or jar of water. You have to fill the hose, stop up both ends, put one end beneath the surface and the other end below the level, but on the outside of the pail. Then when you let go of the ends the water will climb up over the rim of the pail and run out without pumping. R. P. C.

Running Water Up Hill.

I HAVE a 20-acre field which slopes generally to the north. The highest part of the field is about 25 feet above the lowest, which is a meadow. I wish to bring water to the highest part, but am in doubt as to the best and most eeonomieal way to do it. I would use this water for domestic purposes and also to irrigate the upland if possible. I am engaged in large and small fruit, and the high land suffers badly after two weeks of dry weather. J. P. C.

Salem, Mass.

You do not state where you will obtain the water supply you desire to use. If it is from a well or spring on the hillside I should say that a hydraulic ram is the thing to use. Put the ram below the well one foot for every 10 feet you want to elevate the water. Raise the water to a storage tank on the crest of the hill and let it run by gravity down to the house, as well as about the field. If the ram is high enough above the field to be irrigated, the waste water from the ram will do for irrigation purposes. If this is not advisable, pumping from wells or springs on the low lands to a conerete reservoir on the hill may be the best thing to do. It is hard to give details where so little information regarding your farm is furnished. Rams are cheap and reliable, will work day and night without eare or attention and without cost excepting wear and the waste water. A pump would require power, probably a gasoline or kerosene engine. R. P. C.

Deepening Old Ditch.

AN old diteh is to be re-dredged. It contains some water. Shall I take the levels along the edge of the water? Will figuring the amount of excavation be the same as for new work?

Havana, Ill. H.

In re-dredging an old ditch it is necessary to resort to cross-sectioning for computing the yardage of exeavation, in order that deduction may be made for the existing channel. After the center line has been run and elevation of grade line determined at each station, set up where the instrument will command a view of several stations, send the rodman an estimated distanee out, for setting slope stake, obtain the elevation of this trial point, from which subtraet grade line. The result, half the bottom width of ditch, will be correet distanee out from center to set the slope stake if a slope of one to one is desired. In any ease the distance out will be half the bottom width plus the produet of depth by rate of slope. After the slope stakes are set, levels should be taken between them and the eenter stake, that the end area of the seetion may be computed. The mean area of a given section will be one-half the sum of its two end areas; this multiplied by the length and divided by 27 will be the cubic yards in the section. J. F. V. S.

RAKING UP STONE.—Allow me to tell how I do it. I take a potato hook and rake in windrows, and do not make over three rakings in a row; take a team and manure fork, six tines, and fork them up into eart. Half an aere is a day's work if done well. I do it after seeding, then roll. It will be a pleasure to cut the grass on such a lot.

Vermont. J. A. BEERS.

THE MAIL BAG.

Corn Doing Poorly.

LAST harvest I had a field of Timothy and plowed it under intending to put it in wheat, but did not do it. This Spring I plowed it and planted White Cap eorn, but it is not doing well. I have yellow eorn planted in the same field which is doing nieely. Is plowing Timothy under a fertilizer or is it injurious to the soil? W. B. W.

Pennsylvania.

There is nothing about a Timothy sod whieh should injure corn. Part of the field may have been badly infested with grubs or wireworms or perhaps part was not as well fitted as the rest. Probably the difference in the eorn is due to inferior seed of the White Cap.

Bone or Tankage for Grass.

IN seeding down with Timothy and Redtop, would there be any advantage in using bone dust with tankage? Would the nitrogen in the bone last longer than in the tankage? F. C. C.

Maine.

The bone dust would help dry out the tankage, make a better mixture for distribution and add needed phosphoric aeid. Of eourse neither bone nor tankage contain any potash. The nitrogen in the bone is less available than that in the tankage, and would "last longer."

Thickening New Seeding.

I HAVE reeently moved on to a little place here. I find the meadows very light, even the new seeded. Would it be wise to sow more seed on the new seeding to get a better stand for another year? E. A. W.

Rhode Island.

It is doubtful if seattering seed on these old meadows will thieken the grass. Fertilizing will make what grass there is grow better, but we have not been able to thieken the sod without breaking up and reseeding.

Runners from Non-bearing Strawberries.

I HAVE a small patch of the Marshall strawberry whieh is giving me very good returns. I notieed this year that a few of the plants bore no fruit at all, but started in early to send out runners. These plants were two years old this Spring. I am told that runners from these plants will not be suitable to transplant, but must use runners from plants that bore fruit. Can you give me any information in regard to this? G. F. H.

Orleans, Mass.

In our own experience we have found little difference in the runners from such plants and those from fruiting plants. Usually the laek of fruit is due to some injury, and not to any natural habit of the plant. Many experiments have been made, and they usually show that these strong runners from non-bearing plants yield fruit the following season. Various opinions have been expressed but experience seems to be against the theory that runners from sueh plants are unproductive. We would like to have aetual experience from growers.

Time for Planting Cover Crops.

WHEN is the proper time to plant the Fall or Winter cover crops, such as Cow-horn turnips, rye, rape and veteh? If these are planted in July or August will they winter-kill? How early is it safe to plant and not winter-kill? S. J. E.

Fairport, N. Y.

About the middle of August is a good time to seed rye and veteh or turnips. After September 1 will be rather late for veteh seeding, but rye can be seeded up to Oetober.

Damage from Muskrats.

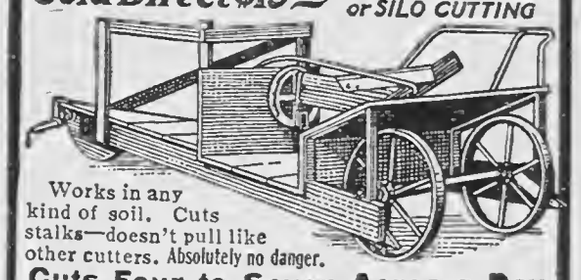
IS there any praetieal and legal way of preventing muskrats from destroying crops? I have some very fertile land along a ereek, and muskrats destroy a large part of the erops every year. Just now they are biting off lots of field eorn that is about a foot high, and carrying it into the ereek. M. F.

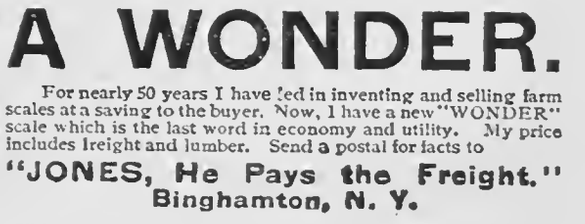
Waterford, N. Y.

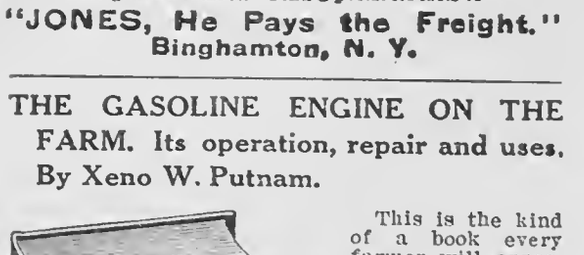
Section 158 of the Conservation Law of the State of New York for 1913, whieh I understand has not been ehanged, provides: "In the event that any species of birds proteeted by the provisions of Section 219 of this article, or quadrupeds protected by law, shall at any time, in any locality, beeome destructive of public or private property the Commission shall have power in its diseretion to direct any game proteetor, or issue a permit to any citizen of the State, to take such speeies of birds or quadrupeds and dispose of the same in such manner as the Commission may provide. Sueh permit shall expire within four months after the date of issuanee."

Under sueh a permit the muskrats eould be trapped or dug out of their holes so as to drive them away. If you do not own both sides of the ereek it would be necessary to get the consent of the adjoining owner or owners.

Poison might be used but the State law in regard to the exposing of poisoned substanees is rather vague, and might be construed to prohibit even the poisoning of rats or mice within a building. A. C. W.







Hope Farm Notes

CHILD BUSINESS.—The question of children and money is often discussed. Some people argue that the child should never be paid for the work it does, and have no individual property. Such people say the child should work (and they usually see that he does), but that he ought to work as a sort of obligation—receiving no money for his labor. At the other extreme I find people who say the child should not do any work, but receive an "allowance" for spending money. Personally I would reject both propositions. I think every child should be taught to do some work. The man who grows up without being obliged to do some sort of labor will be a drone or a parasite all his days. On the other hand, no child should be forced to work all the time. Everyone is entitled to a childhood. and that means a fair proportion of care-free play. The trouble with many a man of 50 today is that he never did know how to play, and he is now too old to learn. He may have reached the condition where he need not work hard if he does not care to, but he never knew how to *play*, and that lack of knowledge affects his life and cuts down its enjoyment.

I mean that our children shall both work and play in fair measure. As for telling a child that it is his duty to work all day to "pay for his board and clothing," I would not do it. You are responsible for the child's being there in one way or another. He is not responsible for his presence, and he is entitled to a fair chance. I think every child should have certain duties or chores to perform, and should be held up to them. He ought to do these things as his contribution to the home, and if it is put at him fairly he will do such work willingly.

When it comes to real labor I would pay the child for doing it, or give him some little business of his own. For example, in picking fruit, I pay our children as I do others. I do not expect the little things to pick all day long, but they do a fair job and get their money like the rest. Out of this money they are expected to buy a few things they need, and they bank the rest. Now I think it much better to pay these children and let them begin to think out business early rather than to have them work for nothing and provide all their necessities. When they see other children paid for picking or similar work while they get nothing, how can they take a full interest in the farm development? You may say that they will get their share later on—but will they get it? A dime in the fingers of a child is worth a dollar far off somewhere in the future.

Little sums of money earned in this way and cemented together by sweat make a little bank account that will not be easily broken up. J. H. Hale tells of one of his boys who worked in this way and wanted to buy a new shirt. He was cultivating corn on a hot day, and as he went on up and down the rows he figured out just how many hot steps there were in that shirt. There were many more steps than stitches. It was far better for him to earn it in that way than to work for nothing and have the shirt given him. Labor is to be a curse or a joy to the grown-up man, according to the way he was made to look upon it when he was a boy. I have started our three small boys in a little business of their own. They organized a company known as

The Hope Farm Boys

One is president, another secretary and the other treasurer and general manager. In the Spring they planted 500 Marshall strawberry plants three feet apart each way, with potatoes in between. Now they are digging the potatoes and potting plants for sale. They advertise in the local paper over their company name, keep their own accounts and do their own correspondence. The treasurer handles the money and divides with the others as often as he accumulates $3. They are likely to do a total business of $50 or more this season, as they own several apple trees which are well covered with fruit. This plan has worked out well thus far. These boys are not inclined to spend their money foolishly. They each have a bank account, and when they are a litle older I shall start them with a check book to make their payments by checks. They are interested in their little business and want to enlarge it. They have now come to one of the great problems of business. Thus far they have done their own work, with such help as I have given them at odd hours. Now they begin to see that in an hour at potting plants they may make $2. With that money they could hire an Italian to do far more hoeing than they ever could, while they kept at the far more profitable work of plant production! Thus this little company comes up against the problem of the ages—the relation of capital to labor. My plan is to encourage these little boys to increase their business slowly, keeping on a solid foundation, paying as they go and not attempting more than they can handle.

STILL RAINING.—The daily showers kept up through July. Hardly a pound of the hay in our neighborhood escaped a soaking. By August 1 large fields of grass were still uncut. There are some farmers who prefer letting the grass stand until it goes to seed. They ought to be well satisfied this year—in fact, this has been a record-breaker for rain. On our heavy soil the long continued wet has started a tremendous growth of weeds. As we could not work the ground properly these weeds got the start in some places, and we are up against a hard proposition. In some of the peach orchards these weeds are waist high. For the Summer this is as good a cover crop as we want. Cultivating or plowing now would be the worst thing we could do for the peach crop. It would be a direct invitation to brown rot and a lot of other diseases. In fact this growth of weeds has been about the best thing that could happen to some of our peach varieties, by stopping the rapid growth of wood. We shall cut around these trees with a scythe and let the cuttings lie on the ground. Then after picking, if it seems best, we can work up the soil with the Cutaway and seed to rye. The truth is that on a number of acres the balance of our hoeing and cultivating will be with a scythe. The soil is now well filled with moisture, and will mature its crops. With everything piling upon men and horses at once we cannot hope to clean up our fields completely. If we can cut off the weeds before seeding and let them lie on the ground we can work faster than with a hoe, save the crops and add something to the soil. Rather slovenly farming, you will say, but there will come times when it is necessary to do strange things in order to fit the weather.

POTATO AND RYE.—Those late planted potatoes are growing well thus far. They make tall upright stalks and grow faster than any potatoes I have seen before. They have been cultivated twice, and will now be hilled up. People who have tried this late planting tell me that small uncut potatoes are best. I took what was left over from the earlier seed. Our regular crop is the most promising we have ever grown. Two acres at the back of the farm, planted in a young apple orchard, are certainly hiding their talents in the earth in a way calculated to win a prize. We could not get all our rye cut before the rains flooded and some of it began to shell out. One big field at the back of the farm is in this condition. Instead of trying to cut dead-ripe grain we shall chop the whole thing right into the soil with the Cutaway heavily loaded down. This will re-seed the field and work in most of the straw. Next year the soil will be in good condition for planting a peach orchard of new varieties which I intend to try out.

LEADING A COW.—Here is a question which certainly appeals to me:

Can any of the readers of THE R. N.-Y. tell me how to lead a cow that never had a rope on her? J. A. D.
Eastport, Me.

I had an experience trying to lead a Florida cow some years ago. We got the cow home, but I never claimed that we did the job in any scientific way. Since then a number of good cow men have told us how to do it. One way is to blindfold the cow. Tie a coat or blanket over her head and face. Unable to see she will follow the halter and rope. Another way is to use two ropes—one round her neck or horns. Make a slip noose of the other and put it around the cow's waist. Bring the end up between her front legs and fasten to the back of the wagon. When she tries to pull back she tightens the slip noose around her body and she will soon go ahead in order to slacken it. Still another scheme is a sort of harness used on horses that "back" when they are tied. This is a leather strap with sharp tacks driven through it put around behind the rump. It is held in place so that when the cow throws herself back she gets into these tacks. If I were starting with another cow I would put a rope around her horns, fasten a blanket over her eyes and tie her behind a wagon.

HILL STRAWBERRIES.—Here is a note from an Indiana man:

I tried your advice given last year about strawberries, and this year raised berries that made people open their eyes. Plants grew a foot high and held berries up off ground in a great many instances, but they got away from me and grew nearly solid. Will try to do better next time; the hill system for me. Our berries brought 15 cents when others sold for eight and 10 in Ft. Wayne. This market gets very few fancy berries. H. H.

The hill system of putting the plants wide apart and keeping the runners cut off works well with some varieties, but would not answer for all. Some varieties are very free plant-makers, and they ought to be grown in matted rows in order to obtain best results from them. I advise the hill system only for those varieties which naturally make few runners. Even with these it is a great job to keep the runners cut off and only a few patient growers will carry the system through. No doubt about it, this is the way to grow fancy fruit. H. W. C.

"AUNT Chloe, do you think you are a Christian?" asked a preacher of an old negro woman who was smoking a pipe. "Yes, brudder, I 'spects I is." "Do you believe in the Bible?" "Yes, brudder." "Do you know there is a passage in the Scriptures that declares that nothing unclean shall inherit the Kingdom of Heaven?" "Yes, I'se heard it." "Well, you smoke, and there is nothing so unclean as the breath of a smoker. So what do you say to that?" "Well, when I go dere I 'spects to leave my breff behind me."—New Orleans Picayune.

E. Frank Coe Fertilizers

1857 THE BUSINESS FARMERS' STANDARD FOR OVER FIFTY-FIVE YEARS 1914

Are You Planning to Increase or Cut Down Your Success?

WITH the present prospect of bountiful harvests this fall should come a full realization of the enormous stores of plant food consumed by crops in their growing.

Successful Crops Can Be Maintained Only By the Same Forces or Elements That Have Been Growing Your Good Crops in the Past

To insure better crops in the future and to guard against so-called "soil-exhaustion" you should use an abundance of the right kinds of plant foods for late summer and fall seeding.

No doubt your chief interest is in profits from your farm and the experience of fifty-seven years has shown thousands of farmers that **E. FRANK COE FERTILIZERS** are real profit makers. Are you not willing to have these superior fertilizers prove this on your farm?

It will pay you handsomely to give especial attention to your grass seeding which should be done not later than September 1st, in order to get the best results.

When actual figures show a net gain of $33.33 per acre, per year as the result of proper fertilization of hay fields, do you not think it is well worth while?

You ought to have a copy of our booklet, **"Seeding to Grass and Clover,"** written by one of the greatest farm workers in the country. The illustrations relative to plowing ought to be worth $100.00 to any farmer.

A copy of this booklet is yours for the asking if you will mention the name of your farm paper when you write.

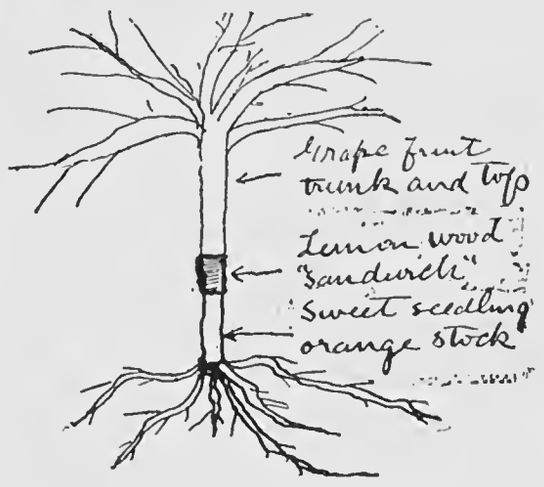
CITRUS TREE SANDWICHES.

THE term "sandwich" in my last report on the progress of our work in the improvement of Citrus fruits by bud selection was used to describe a tree condition more or less common in Citrus orchards. This condition might be illustrated by the following description of the method of propagation resulting in their condition.

For example a sweet or Mission orange seedling is budded to lemon, say the Eureka lemon, and the bud allowed to grow one or more years in the nursery. For some reason it becomes desirable to rebud this lemon tree to grapefruit. The grapefruit bud is inserted in the young lemon tree, usually several inches above the union of the lemon and orange seedling wood. The resultant tree then is made up of sweet seedling orange stock, a section several inches thick of Eureka lemon wood in the trunk, and the remainder grapefruit trunk and top of tree.

The section of Eureka lemon wood in a tree of this character was called "sandwich" in order to distinguish it from the normal tree condition, which would have been sweet seedling orange stock and grapefruit trunk and top of tree. This condition might be illustrated by the following diagram.

In some cases, such as Citrus varieties having characteristically different rates



of growth, the sandwich grows either more rapidly or on the contrary more slowly than the stock and top, in which case it can be seen protruding or receding from the horizontal lines of the grapefruit and seedling orange trunk, above and below the "sandwich."

In a navel orange orchard near Riverside in which we located a Citrus performance record plot in 1909, we found in 1912, such a condition. In this case sweet seedling orange stock was used, which had originally been budded to lemons about 1898. The young lemon trees were rebudded in 1899 to navel orange buds, about five or six inches above the point where the lemon buds had been inserted the year before.

This orchard in the period 1909 to 1912 deteriorated so rapidly in amount and character of fruit production as to become almost useless. While studying these decadent trees in our plot, I happened to notice one day lemon sprouts growing out of the tree trunk. On investigation I found that these lemon sprouts came from a lemon "sandwich" in the tree trunk as a result of the method of propagation mentioned above. A comparative orchard across the road, in which we had a performance record plot, did not deteriorate, and upon examination was found to be free from lemon "sandwiches."

The owners of the orchards became convinced that there was a relation between the decadence of the orchard with the lemon wood in the trunks and the presence of this lemon wood section or sandwich. They then cut back the orange trees, cutting off the trunks *below* the sandwiches, and inserting navel orange grafts in these sweet seedling orange stumps. In other words they eliminated the sandwiches.

It is too soon to report on the results of this experiment. However, acting on this hint, we have looked in many orchards, particularly decadent orchards, for the sandwich condition as shown by trunk sprouts or differences in rates of growth. We have enough evidence to say safely that in many cases it looks as though there might be a relation between tree condition and the sandwiches of other varieties in the tree trunks. This seems particularly true in the orchards examined of sandwiches of Valencia orange or lemon wood in navel orange trees.

Just how this condition might be responsible for tree conditions it is impossible for us to state. We might suggest the differences in hardiness of the "sandwich" and the tree, so that in cold weather the sandwich might be affected more than the fruit or tree. There is no doubt also that varieties of Citrus differ in their resistance to environmental conditions other than temperature, which might explain in some cases a possible correlation of "sandwich" condition and certain forms of orchard decadence.

In all studies of the relation of stock to scion this possible condition should be kept in mind. The practice of rebudding nursery trees is more or less common, changing from one variety to another as a result of fluctuating tree market conditions. It is possible that under certain conditions this practice might be dangerous, although we have no positive proof as yet that such is the case.

A. D. SHAMEL.

Grafting or Budding Roses.

WILL you explain the process of grafting or budding, a wild rose branch or root being used as the foundation? Some of my hybrid roses have died, but the roots have sent up wild roses. F. W. L.

Tuckerton, N. J.

The stock commonly used for Hybrid Remontant roses is the Manetti, a variety of the China or Bengal rose, with deep pink single or semi-double flowers, though brier stock is also used. In this country budding in the open air is done in June and July, a dormant shield bud being used. The stocks, which come from France, are trimmed back closely, both root and tops, planted in Spring, and budded the following Summer, whenever the bark peels readily. The process is similar to any other budding as to careful fitting and tying of the bud. The bud remains dormant that season, but starts into growth the following Spring, when the top of the stock is cut off. We infer that the inquirer wishes to bud upon stocks of his old plants, but we are unable to say whether this would be satisfactory, as we have never tried it. Evidently suckers or sprouts were permitted to grow, which being stronger than the budded plant have starved it out; such suckers should always be removed. We are often told of rose bushes that have "reverted to wild roses," when of course this is the trouble. We like to set our grafted roses with the ground level just above the union; then, as natural roots are formed, we have an own-root plant.

Root-grafting is very commonly employed under glass, either cleft or splice-grafting. Bits of root two or three inches long are united with scions of similar diameter. The grafts are covered with moist moss and left in a cool house or frame till united, when they are potted and grown on until planted out in May, the work being done, of course, in Winter.

Azaleas, Violets and Freesias.

I ENCLOSE a branch from a plant that I have which I would like identified. The plant in question is about 12 years old, a regular tree form, but never has any flowers. 2. When and how are sweet violets put in cold frames to get flowers in February and March? 3. How is the Azalea treated after flowering, and when re-potted? 4. Can I force Freesias in hotbeds made of brick? If I want them at Christmas, when are they put in?

Tarrytown, N. Y. T. W.

1. The plant sent was Crassula portulacea, a native of South Africa. It grows into a bush four or five feet high, and does not usually bloom under glass until it is older than the specimen named.

2. February and March are the natural flowering time for the violets grown under glass, and unless sunlight is very deficient it should be quite easy to get an abundance of flowers from plants set in the frames in September. Some growers set the young plants directly in the frames where they are to grow and bloom in Spring or early Summer, leaving the frames open all Summer, while others plant them in the open ground and put movable frames over them in the Fall, this being adapted to sections where the climate is less severe. The best place for violet frames is on ground sloping to the south, with some wind-break at the north.

3. The best time for re-potting Azaleas is after flowering, when new growth starts. Soil is a sandy compost of half peat and half leaf mold, with some good fibrous loam added. The plant must be potted firmly, the base of the stem just above the surface, and the soil well rammed down the side of the pot; ample drainage must be supplied. After flowering, the seed pods should be pinched off, and the plant treated as before until danger of frost is past, when it should be put outside in a frame or sheltered spot, the pot plunged in coal ashes to prevent drying out. In such a situation Azaleas should be well watered, vigorous spraying with cold water preventing red spider, and they make a very fine growth. In September they should be brought inside, and it is quite common to re-pot them at this time, though it may be done earlier. An open slatted shed of lath is a good shelter for Azaleas in Summer.

4. Freesias are very easily forced, but we have had no experience with their culture in hotbeds. As a brick hotbed is referred to, this inquiry may have reference to a heated frame; we do not think a hotbed heated with manure would produce Christmas Freesias at Tarrytown. Freesias for forcing are potted in succession from August till February, giving a period of bloom that lasts from Christmas until June. They are usually in bloom about six weeks after top growth starts. They need careful watering until the plants are in flower.

Grafting Old Apple Tree.

AT a farm which I have in the State of New York there was once a large Flemish Beauty apple tree. Some years ago, while overladen with fruit, one of the large limbs broke and the tree was neglected. Eventually worms gained access to the other branches and destroyed the tree. The stump left is about two feet in diameter and 6½ feet high, on the side of which there is a live strip running to the top of the stump. Out of this at the extreme top there is a perfect tree growing, which is about five feet high and 1½ to two inches thick at the butt. Can I save this new tree by cleft-grafting it to another stump, or would you suggest grafting the whips to some other tree? If possible I would like to keep this tree intact, as it is perfectly formed.

Staten Island. J. O. K.

There is no such variety of apple as Flemish Beauty but there is a pear by that name, but whether it be a pear or apple tree makes no difference. A sprout on the side of a stump two feet in diameter does not seem to be the beginning of a very substantial tree. The stump being dead it will rot away gradually and the sooner it is gone the better for the sprout. It might be well to cut out all of the dead wood and leave the living part in such condition as to grow into a healthy body, provided it will do this. A small post as a temporary support beside the trunk might do good until the growth made it substantial. If two young apple trees were planted beside the living part and grafted to it in a dexterous manner a sort of triple or tripod trunk might be formed that would be substantial and a curiosity as well. This would require skill and constant care that sound unions be made and the final cutting away of all dead wood from the old trunk. It would be a tree on crutches.

H. E. VAN DEMAN.

WANT TO KNOW.

OVERHEAD IRRIGATION FOR BERRIES.—I would like to know whether any of the readers of THE R. N.-Y. have ever used overhead irrigation on strawberries and bush fruits, and with what success. I have seen this method of applying water to all kinds of vegetables with splendid results, but am told that it will not do on berries as it will scald both fruit and foliage. My crops of berries were ruined both this year and last by drought and if I can find a system of irrigation that is successful and practical, I would like to know what it is. I am located so I can get city water and at a reasonable rate.

Indiana. S. D.

Amatite ROOFING
Perhaps the greatest advantage of Amatite roofing is the fact that it *does not need painting*. Amatite has a durable mineral surface that resists wear and is absolutely waterproof.

Save Work, Time, Money
By using our low down steel wheel wagon

Electric Handy Wagons
saves high lifting, lighten draft, don't rut roads. Spokes don't loosen—wheels don't dry out or rot. Write for free book on Wagons and Wheels.
Electric Wheel Co., 48 Elm Street, Quincy, Ill.

FREE TRIAL 30 DAYS
BESSEMER KEROSENE ENGINE
Success with cheap kerosene or coal oil absolutely guaranteed. Try before you buy. Most economical, reliable and durable engine made. So simple and easy the wife or boy can start and run it. People everywhere throwing away their old engines, buying Bessemers and making money by it. Get one for yourself. Be ahead of your neighbors. Runs fast or slow. Will do a dozen things at once. Wonderful beyond belief. Pays for itself in fuel saved. For special discount write at once.

THE BESSEMER GAS ENGINE CO.
123 LINCOLN AVE. GROVE CITY PA.

INOCULATE
ALFALFA
Crimson Clover and Winter Vetch. Write today for instructions to obtain larger yields by the use of Farmogerm. Our free illustrated booklet No. R. N. 10 contains valuable cropping receipts and is yours for the asking.

THE RURAL NEW-YORKER.
333 WEST 30th ST., NEW YORK.

Ellis Champion Threshers
Be Your Own Thresherman
Save enough to own the Thresher. Be independent. Do the work when you get ready.
Suit everyone. Both the professional thresherman or the farmer who wants a home outfit will find the Champion rightly named. The picture shows ELLIS CHAMPION No. 2. It is complete with stacker, tailings, elevator and grain bagger. Connect it with steam, gasoline, tread or any other power, put in the grain and the Champion does the rest. No straw clogging. Any size.

We also make tread and sweep horse-power, drag or circular saws, ensilage cutters, corn shellers, etc. Our catalog tells the whole story.
ELLIS KEYSTONE AGRICULTURAL WORKS, Pottstown, Pa.

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York
HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 75 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

A FARMER in Texas undertook to make his Congressman see a joke. So he wrote for some free seeds and suggested a package of macaroni seed. The solemn M. C. took this farmer right at his word and wrote back:

I have ordered the seed sent you from the Agricultural Department and wish to congratulate you in your efforts to grow this very valuable plant. It is the cultivation of macaroni that paid the war debt of Italy and has made it one of the wealthiest nations in the world. I do not see why the rich soils of Red River County would not grow this to the extent of making it, in connection with their long staple cotton, the wealthiest agricultural spot on the globe.

The Italians paid their war debt by eating macaroni rather than by planting the seeds—but what is a little thing like that to a Congressman? If he can plant a macaroni seed and raise a vote it is certainly a productive seed. But he cannot fool the farmers any more, or buy them with a 10-cent package of seeds!

*

THERE are hundreds of farmers who are feeding a well-balanced expensive ration, and are reducing the efficiency of this feed 25 per cent by swearing in the barn, and pounding home runs against the cow's ribs with the milking stool. The long and the short of such business is that it does not pay. When the discriminating farmer goes out to buy a cow, or when he retains one in his herd, he considers her intelligence. Bovine phrenologists say that a cow wide between the eyes is an intelligent one, and intelligence and nervousness go together in the dairy cow. The better the cow, the more marked the effect on her production will unkind treatment become. The farmer who wants to get out of the scrub class must treat his cows right. The farmer who is kind to the children, is considerate of his wife, and is willing to coöperate with his neighbors is the man who will make a success with the dairy herd. The man who stones his cows when he drives them to and from the barn would better keep out of the purebred business, for he will lose out.

*

THE Geneva Experiment Station has issued what seems to us a very sensible bulletin on purity of farm seeds. Among other sound advice in this bulletin is the following in reference to samples of seed which are adulterated with weed seed or trash.

If the seed appears to contain considerable amounts of such rubbish, the buyer should insist that it be cleaned before he takes it, secure a reduction in price proportionate to the amount of impurity, or look elsewhere for his supply.

That is sound common sense. If any farmer receives a sample of seeds loaded up with chaff or gravel or weed seeds, he ought not to accept it at all, or if he does take it he should not pay the price of pure seed. Yet in "Horticulture" Geo. C. Watson is reported as trying to ridicule this sound advice.

In other words, according to the authorities of the great State of New York, the cleaner the seed the smaller the price! The worst of it is, New York is eminently fair compared with some other States—and Washington. The foregoing extract is from Bulletin 378 of the Geneva Station. The same bulletin enlarges on the law not being drastic enough—like the fertilizer and foodstuff laws. As if seeds could comply with such conditions! Seeds are not a manufactured product, and attempts to apply such laws to them are unjust and ridiculous; and do more harm than good to the farmer and all concerned.

It is hard for us to believe that Mr. Watson ever made any such statement. The mixed and "loaded" samples of farm seeds which some of our readers have received are certainly "manufactured"—as much so as fertilizer. There is no reason why seeds should not be guaranteed the same as fertilizer. Our farmers are entitled to full inspection and protection. The Geneva Station is doing good work in this line and should be supported—not sneered at

CAN wheat be used at all for cow feed? We have a good crop of wheat with the usual low prices in prospect, and would like to feed it if possible. What could be mixed with it to feed milch cows with corn fodder and mixed Timothy and clover hay for roughage? C. D. H.
Ohio.

Letters are coming from all over the West asking about feeding wheat. The "bumper crop" talk has had the effect of pushing down prices. The authorities now say that the world's total supply is not large and that much of our surplus wheat will be needed in Europe. The "bumper crop" talk, however, has cut down the price to farmers, and thousands of bushels will be fed to stock. Wheat has much the same composition as corn. It does not make as good a feed as corn when crushed, as it is too sticky or pasty to feed alone. Many an old time farm boy will remember how hungry he was when he got up to milk and do the chores before breakfast. We often chewed a handful of whole wheat until it made a sticky paste of gluten in the mouth. Barley, oats or corn ground in equal parts with the wheat relieves this pasty condition and makes a good mixture to feed with Alfalfa or clover hay and silage. Should there be a war in Europe the price of flour and wheat for export will rise, but the "bumper crop" talk, as was intended, is getting the wheat out of farmers' hands at a low figure. You will find a full discussion of the feeding value of wheat in THE R. N.-Y.

*

WE have now waited for several months for the proof that those English Wyandottes at the egg-laying contest are hybrid or mixed breeds. No proof has been forthcoming. We have given illustration from the possible breeding of several breeds of cattle to show what might happen as the result of long-continued selection for dairy production. Now we have the following:

Your simile of Jersey cows is not fair. Barron started with a pen of Brahma-Hamburg-Leghorn hybrids bred to blocky shape, and in 15 years he has produced splendid layers of a very different shape. They are "Barrons," or "English" of a distinct type and are entitled to a name. BUCHANAN BURR.

How do you know what he started with? The Wyandotte is a "made" breed produced by mixing the blood of several distinct breeds and then selecting for a certain type. We presume that is what is meant. Now many years ago the Jersey breed was "made," as was the Short-horn or Ayrshire, and there are now several distinct types. We can easily find purebred Jersey cattle in Northern Canada and in Texas, which vary as far from the true Island type of Jerseys as those English Wyandottes do from the standard. In the far North or the far South these Jersey cattle have been adapted and selected so as best to meet the needs of climate or dairy practice, but no one thinks of saying they are not Jersey cattle, because such selection has taken them away from the Island standard. They are more useful animals because they have been changed. In speaking of the origin of the curious Egyptian race the historians say:

"It is said that the highly-developed greyhound was useless as a hunting dog till crossed with a strain of bulldog—an infusion of blood, which, while not marring the distinctive physical peculiarities of the hound, yet quite sufficed to supply the lacking stamina and courage."

We have heard speakers attempt to make an argument for special breeds of cattle by saying that men do not select a bulldog to hunt rabbits. It seems that they may select the spirit of the bulldog after all! We have no personal interest in these English Wyandottes. We think the American Leghorns will beat them out before the contest ends. The fact seems to be evident, however, that these English birds are very superior layers, since they have been bred definitely for the one point of egg production. It will be safer to breed this strain by itself rather than to attempt crossing it with the Wyandotte as usually found in this country, but we think it a rather narrow and small proposition to try to belittle or discredit Barron's work in developing this strain.

*

AGRICULTURAL college students as farm workmen! It is evident that many of our readers have tried these young men as managers or farm helpers, and we have received a number of reports. The great majority of them are unfavorable. It appears that a good proportion of these young men are willing to work and are energetic and honest. Too many of them have a very large idea of their own value. They lack experience and the ability to adapt themselves to local conditions. They have been trained at the college to do work in a certain way—usually with the aid of expensive and very complete fixtures. When they go to a practical farm which, being run for business, must cut out experiments or superficial things, many of these young men lack the power to adapt their college training to their new surroundings. In too many cases the trouble seems to be that the college teachers spoil these boys by giving them too large an idea of their own importance. We have heard of cases where teachers advised these untried young men never to accept a place for less than $75 per month, and never to touch any smaller job than that of managers. It would be hard to think of any more foolish advice than this. It will be clearly evident to any business farmer that what these boys need most of all is practical knowledge of real farm operation. How can anyone manage farm labor successfully unless he know *how to do the work* to the best advantage? It is not enough that the college has taught him *why* it should be done—he must know how if he is to make a farm pay—for only by knowing how can he learn to adapt his science to local conditions. The cool-headed and unprejudiced reports which come to us indicate that the training which many of these young men are receiving has given them too large an idea of their importance and value to a practical farmer. It would be far wiser for them to work as plain hired men for a year or so before attempting to "manage" a farm.

*

CALVIN J. HUSON, New York Commisioner of Agriculture, has written the officers of the county and town fairs advising against exhibits of swine. It is evident that last year hog cholera was spread through infected animals shown at the fairs.

I am reluctant to reach the conclusion, but I feel that we had better omit the swine exhibit at our fairs this year than run the risk of scattering the disease throughout the State. I therefore respectfully urge upon officers of agricultural societies the propriety of withdrawing their premium lists for swine, and to refrain from having an exhibit of swine at their fairs this year. Where fairs are held in communities where no cholera has existed within the past year, it might be safe to have an exhibit of swine, provided the entries were limited to such territory as is known to be free from the disease; but to permit an exhibit from infected territory is exceedingly dangerous, and might spread the germs of the disease into territory where the disease has not heretofore existed.

Hog cholera has never been very prevalent in New York State and every precaution should be taken to prevent its spread. Wherever it appears the disease should be stamped out, or it will prove a calamity, especially in our thickly settled farm districts.

*

ON January 1 of this year a new land law went into effect in Egypt:

The law renders properties of the area of five acres and under unattachable for debt. A land mortgage has heretofore been a source of easy credit for the small cultivator. There is no doubt that the funds borrowed by the Egyptian small cultivator on land security have for the most part not been spent for economic necessities, but rather for maintaining a relatively extravagant standard of living. The purpose of the law is to eliminate or at least to minimize this unproductive expenditure of borrowed funds and gradually to relieve the small farmer from his present excessive burden of high interest-bearing debt.

The farming of Egypt is peculiar because nearly all the agricultural wealth is represented by these small farmers. The entire system of farming would be upset if these small holdings should be taken from the present farmers and put together into large farms. In many cases the first chance to obtain easy credit leads farmers without much experience to borrow not to invest but to *spend*. Before they learn just what that means their credit is gone and their farms follow. This law in Egypt will make it harder to borrow for spending purposes. Since the creditor cannot take the farm in case of default he will be sure the money is to be spent for improvements before he lends it.

BREVITIES.

WE cannot see that the song birds have decreased in numbers.

WE know a number of persons afflicted with laziness who advocate the "rest cure."

HIGH living at low cost comes to the man with a good garden and a roost full of fat hens.

THAT was good farming to sow peas and oats. It suits farm stock from brood mares down to shotes.

IF you would have the waste of plant food stop through the wet Autumn—sow a cover crop.

LIGHTNING never strikes twice in the same place, because there usually isn't any place left.

THE disease known as pine rust lives part of its life on the domestic currant. The New York Experiment Station finds that the disease does not survive the Winter on the currant.

THERE has been quite a little discussion regarding the best material for filling the cavities in decayed trees. A mixture of one part asphaltum and three to four parts of sawdust has given good results in Ohio.

IT is said that American meat packers are reaching out as far as Manchuria after poultry. From October to March fowls can be purchased in that country at from 15 to 20 cents each. Dressing costs one-half cent. The plan is to buy such poultry, feed it for about three weeks, dress and freeze and then export.

OPENING OF THE CAPE COD CANAL.

LAST week witnessed the opening of the new canal dug across the neck of Cape Cod. For the past few years the work of digging this canal has gone on very quietly. Not much attention has been paid to it, since the Panama Canal was a much larger proposition, and one which had absorbed public attention. Yet this Cape Cod Canal is sure to have a great influence upon the commerce of the Atlantic coast, and will prove a great convenience and developer of business. Ever since the Pilgrims made their settlement at Plymouth, there have been dreams of such a canal. It is said that Miles Standish, the captain of the small Plymouth army, was something of an engineer, and that even in his day he saw the possibilities of this ditch across Cape Cod. The outside of Cape Cod is the most dangerous point along the Atlantic coast—worse even than Cape Hatteras. In time of storm it is a wild and dangerous trip past Cape Cod, and a very large proportion of the losses to shipping along the coast have occurred there. The opening of the canal marks the beginning of a protected water route between New England along the sound of Long Island to New York City. The distance is shortened by many miles, and vessels can travel in practically all kinds of weather. Looking beyond the present there are still greater possibilities. For the last century, wise men have seen the advantage of an inside water route all the way between New England and Florida or the Gulf of Mexico. Such a route would cross New Jersey and on to Chesapeake Bay, then down across Virginia and North and South Carolina to Savanuah or Jacksonville. A glance at the map will show the many rivers and inlets which may be utilized for such a route. Congress has started again and again to provide for such a passage, but for one reason and other it has always been given up. The present Congress is said to be in favor of such an enterprise, and in the course of time it will without question be worked out. In such an event a vessel can start from Portland, Me., or Boston, Mass., pass through the Cape Cod Canal and along Long Island Sound and then journey in safety, protected from severe storms, or from the ravages of a hostile fleet, down through the country to the Gulf of Mexico and if need be to the Panama Canal. Such an inside waterway would prove a great safety and convenience and a wonderful development of the Atlantic coast region. It is coming in time, and for that reason, if for no other, the opening of the Cape Cod Canal is a great event in the commercial history of New England and the Atlantic coast.

The Connecticut Poultry Meeting.

THE meeting of the Connecticut Poultry Association held last week at the Connecticut Agricultural College was probably the most interesting if not the largest gathering of poultrymen ever held in this country. The close egg contest between the English Wyandottes and the American Leghorns has created deep interest. Added to that was the fact that Tom Barron, the English poultry breeder, was to attend this meeting and make two or three addresses. There has been a great desire among poultrymen to see and hear Mr. Barron. The result was that all the hen men who could do so travelled out to Storrs. The Connecticut Agricultural College is a hard place to reach. It is located in a rough country, nestling among the hills far from the railroad. Still over 600 people gathered at this place, some coming in wagons, others in automobiles or in any conveyance possible. It is safe to say that a good proportion of these people came prepared to scoff and remained to pray. A good many of them have been sceptical regarding the value of these egg-laying contests, and a great many of them had somehow formed the idea that there was something wrong about Tom Barron and his birds. It is safe to say that all of these people went home impressed with the value of the contest, and agreeing that Mr. Barron is a plain, straight, honest man, whose knowledge of a hen and her ways has been learned by hard and patient experience. There was a fine program, but the best part of the whole meeting was the long trip through the egg-laying contest. The leading pens were visited, and Barron and others explained their methods of selecting hens in an effort to pick out the good layers from the drones. This was thoroughly interesting to the crowd, and all through the day there might be seen little groups of men and women scattered about the college grounds discussing this great question of throwing out the drones, and how to improve the laying qualities of the hens.

There was no building on the grounds large enough to contain the great crowd. Everyone was good-natured and happy in spite of the fearful weather. We shall try to give a full account of the meeting later, and a good synopsis of Mr. Barron's talk regarding the breeding and selecting of a laying hen. As is usnally the case, a talk by such a man is in a class by itself, and one must hear and see the man himself in order to get a fair idea of what it means. No printed report of such a thing could really do full justice to it.

New Jersey Organization.

THE new State Board of Trade and Commerce of New Jersey promises to be of great good to the farmers of the State. The objects of the new federation are to take concerted action on State-wide problems, to make the federation a clearing house for the latest thought and experience in civic and commercial work, to analyze and take constructive steps in regard to such matters as agricultural and industrial development, civic and social conditions, residential and recreative facilities, water-ways, city planning, good roads, municipal research, community publicity, vocational education, retail credits and many other lines of activity; to advance the prosperity and prestige of New Jersey through the increased efficiency of its several communities, and to build up public opinion that truly reflects sound economic principles. It is understood that steps will be taken at once to investigate such rural problems as consolidation of schools, transportation of pupils, purchase of school supplies, salaries and cost of living of country school teachers, marketing and transporting of farm produce, co-operative purchasing of fertilizers, seeds and farming utensils, farm and domestic help, libraries at convenient local centers, etc. This work of investigation will be done by trained experts.

D. T. H.

New York State News.

CONFERENCE OF CO-OPERATIVE SOCIETIES.—The chief event in farm circles the past week was the first annual conference of co-operative associations of the State, at Utica, called by Commissioner Huson, and presided over by Marc W. Cole, Superintendent of the Bureau of Co-operation. It was an informal meeting in respect to the program as there were no set speeches, but rather was it a comparing of notes on the work of the co-operative societies of the State, there being representatives from nearly all these associations as well as from other co-operative societies not organized under the new State law. The question box and the round table were important features of the meeting. Superintendent Cole stated the purpose of the meeting to be to crystallize into a brief statement to be made to the Legislature at its next session, some of the things thus far accomplished by the bureau of organization, and other things it hoped to do, in order that the Leliglature may be well informed as to the necessity of such a bureau and of the growing importance of co-operative societies. Certain amendments to the co-operative law were also to be considered. It is probable that at the next conference, which will be held in Utica in December, more definite information as to the working of the law and the need of its amendment in certain respects, will be available. The reports of the representatives of the various State co-operative societies will be included in the bulletin to be published in a few weeks which will contain a complete report of the proceedings of the conference.

FARM HORSES AT STATE FAIR.—It looks now as if the department of farm draft and breeding horses at the State Fair this Fall would break all records. Premiums aggregating something over $9,000 in the 194 classes will bring out a fine lot of animals. Besides the money premiums there are gold and silver medals offered champions by the Belgian Society of Brussels, the New York Belgian Society, and the Hackney Horse Society. The Percheron Society of America offers gold and silver medals. This show is of especial educational value to farmers and stockmen, for whom it was established some years ago.

STATE FLORAL CLUBS.—The annual meeting of the State Federation of Floral Clubs will be held at Syracuse, September 3, during State Fair week. It is probable that Dr. Beverly T. Galloway will be the chief speaker before the federation. Dr. Galloway was for many years chief of the Bureau of Plant Industry at Washington before becoming the head of the State Agricultural College at Ithaca. The federation is composed of all the professional and amateur flower clubs of the State.

BIG WEEK FOR THE CHEESE MEN.—The meetings of the Watertown Produce Exchange on Saturday, July 25, witnessed the big week's work of the season when 8,520 boxes of cheese were sold at 14 cents per pound, making an approximate total of $57,000.

OUR STATE MINES.—While New York has no gold mines it has a very considerable mining industry, as is shown by the report of the State Geologist, recently issued. The aggregate value of ores and mineral materials for the year 1913 was $41,704,020, an amount larger by several millions than the total reported for any preceding year. Iron ore was worth $3,870,841. There are two rock salt mines and about 25 evaporating plants in active operation which turned out 10,819,521 barrels of salt, valued at $2,856,664, the largest on record. Natural gas contributed $2,549,227 to the total and petroleum $2,255,508. Portland cement was produced to the amount of 5,146,782 barrels, valued at $4,873,807. Clay materials produced a value of $12,077,872, and stone products had a value of $6,763,054.

J. W. D.

Grasshoppers and Grandfathers.

A PRESENT PLAGUE.—We are receiving vigorous complaints of the injuries of grasshoppers and urgent requests for aid in checking the ravages of these hungry hordes of insects. All of the outbreaks of these locusts that we have investigated so far have been confined to regions having a sandy or gravelly soil. Yet the outbreaks are so widespread and so serious that the situation is worthy of some general consideration.

THE KIND DOING THE INJURY.—In the first place, we find that the species of grasshopper causing nearly all of the trouble is the lesser migratory locust (Melanoplus atlanis), a close relative to the notorious Rocky Mountain locust that devastated the fields of Kansas, Missouri and other Western States in the seventies. This locust is widely distributed over nearly the whole United States, and is apparently one of our common grasshoppers in New York State. We refer to this commonness of the insect in order to emphasize the fact that the injury being done now is not due to the work of any new or extraordinary pest, but is due rather to the unusual development of a common and well-known insect. Moreover, as we shall point out later, this unusnal development has probably been fostered by lax methods of farming. In order to understand the relation that exists betweeu the development and inerease of this insect and the usual methods of farming, it will be necessary to know something of its life history.

THE LESSER MIGRATORY LOCUST.—In the fields where the swarms of the locnsts are to be found at this time (June 26), a large number of them will be seen to possess wings. This means that such individuals are now full-grown. There are, however, many of them without wings. These are the young, immature individuals that we call nymphs. Probably by the first of July a majority of the locusts will be full-grown, with fully developed wings. They will then be capable of migrating from one field to another, in fact, for consuderable distances. It is not definitey known just how long before these adult locusts will begin to deposit their eggs. Observations indicate that they will be laying their eggs the latter part of July and first part of August.

METHODS OF CONTROL.—There are temporary methods of controlling an outbreak of these locusts that will furnish considerable relief and protection to the crops immediately menaced. One of the most successful methods of obtaining temporary relief from the injuries of grasshoppers is by killing them with poison baits. In Kansas, where locusts often become a plague, a new poisoned bait was used last year on a large scale, and with most gratifying success. Professors Dean and Hunter of Kansas give most interesting and enthusiastic reports of their use of this bait which is made up as follows: Bran, 20 pounds; paris green, one pound; syrup, two quarts; oranges or lemons, three fruits; water, 3½ gallons. The paris green and bran, while dry, are thoroughly mixed in a washtnb. The juice of the oranges or lemons is squeezed into the water and then the skin and pulp of the fruit is chopped up fine and added to the water. The syrup is also added and then the bran and paris green are thoroughly wet with this mixture. This bait seems to be very attractive to the locusts and succeeds in poisoning them in immense numbers. It is sown broadcast over the infested fields early in the morning. The locusts do not eat it readily after it becomes dry, hence the early morning applications. Some judgment must be used regarding the places in which the bait is to be scattered. For example, in Alfalfa fields it would be best to cut the crop first and then scatter the bait. The same would probably be true of meadows. In all cases the bait should be scattered where the insects are thickest or in their path if they are migrating to new fields. The amount of bait indicated by the formula given should be sufficient for about five acres. In the long run, however, one cannot afford to fight grasshoppers, at least, in New York State, by the use of poisoned baits. It is extremely desirable to employ a method that will permanently rid an infested area of these voracious pests.

GOOD FARMING A REMEDY.—We have emphasized the fact that the eggs of these grasshoppers are laid in the soil; that they are laid in ground that is fairly compact, for example, in old pastures and meadows, along fence rows, ditch banks, and similar places; and that the eggs lie over Winter in the ground. It is evident that a system of farming still carried on as our grandfathers carried it on, namely, one in which the pastures and meadows and fence rows are maintained world without end, is especially conducive to the welfare of grasshoppers. A run-out meadow, a century old fence or an old pasture bare of grass in a sandy region is an ideal place for grasshoppers to deposit their eggs and to increase in undisturbed tranquility and happy felicity until a season comes when their opportunity arrives and they appear in hordes. On the other hand, it has been shown that the eggs of grasshoppers can be destroyed by plowing and harrowing the land in which they are deposited in the late Fall or early Spring. Therefore, it happens that the man who practices a modern three or four-years' rotation, even in a sandy gravelly region, is largely protected from the ravages of these insects. This was brought most forcibly to the attention of the author in an investigation of an outbreak of grasshoppers in central New York. A small farm which the author visited had literally been cleaned of Alfalfa and other crops, while on an adjoining farm on which there had been in practice a modern rotation there was no serious injury. No object lesson could have been plainer or more convincing. The only practicable way for the owner whose crops have been destroyed, to obtain a permanent control over the locusts, is to plow and harrow every foot of land possible on his place this Fall or early next Spring before the eggs hatch. Fall and early Spring plowing and harrowing, then, is the most important method of permanently controlling locusts in New York State. In conclusion it may be said *that the more intensive a system of farming becomes the less extensive will be the outbreaks of insect pests.*

GLENN W. HERRICK.

N. Y. College of Agriculture.

Government Crop Report.

CONTINUED excessive heat, with deficient rainfall and more than the usual sunshine over the principal crop-growing sections, made this the most trying week of the season on crops now at critical stages of growth.

In the Winter wheat sections harvesting is largely completed, and dry weather favored thrashing which is under way in the central and northern portions. Plowing for next year's crop has begun.

In the Spring wheat States dry and hot weather were somewhat unfavorable in North Dakota, and damage from rust is reported from western Minnesota. In other sections the crop is generally suffering from heat and dronth.

In the corn belt the week was generally unfavorable in States to the eastward of the Mississippi, except in the more northern districts. Drouth still continues in Missouri and Oklahoma and it is getting dry in Kansas, Nebraska and Iowa, although the crop is generally in excellent condition in the last-named States.

In the Ohio Valley drouth is again severe and much damage has been done, while farther eastward in the Atlantic Coast States rain is now badly needed in many portions.

Harvesting of oats is nearing completion in the northern districts, with a poor yield. Damage from rust is reported in many localities.

In cotton-growing States showers over the eastern and central portions of the belt maintain a generally good condition of crop, but many localities were without sufficient rain and plant is now beginning to suffer.

In Texas and Oklahoma hot and dry weather the greater part of the week prevented any improvement in condition of cotton crop over large areas, and growth is generally at a standstill, with considerable deterioration in sections where drouth is severest.

Good showers in Florida improved conditions, and late crops are doing well in some other southern localities, but rain is very generally needed in all trucking districts.

Over the Atlantic Coast States, from Virginia northward, the week was hot and dry over the southern portion, and corn, tobacco and other crops are being seriously affected. In the more northern portion cooler weather prevailed, showers for present ueeds occurred very generally and crop growth progressed satisfactorily.

Over the Western plains region and the mountain and plateau districts the ranges continued in excellent condition, especially in the southern portion. Forage crops of all kinds are making satisfactory growth. The fruit outlook is good and water for irrigation continue plentiful.

Over the Pacific Coast States the weather was favorable for harvesting hay and Winter wheat in Washington and Oregon, but it continued too dry for spring wheat, which is now suffering for rain.

In California crops made satisfactory progress and the drying, canning and shipments of fruit progressed as usual.

Woman and the Home

From Day to Day

If We Had But a Day.

We should fill the hours with the sweetest things
If we had but a day;

We should drink alone at the purest springs
In our upward way;
We should love with a life-time's love in an hour
If the hours were few;
We should rest, not for dreams, but for fresher power
To be and to do.

We should guide our wayward or wearied wills
By the clearest light;
We should keep our eyes on the heavenly hills
If they lay in sight.
We should trample the pride and discontent
Beneath our feet;
We should take whatever a good God sent,
With a trust complete.

We should waste no moments in weak regret,
If the day were but one;
If what we remember and what we forget
Went out with the sun;
We should be from our clamorous selves set free,
To work or to pray,
And to be what the Father would have us be
If we had but a day.

—Mary Lowe Dickinson.

*

PERHAPS there is a little moral in the anecdote of Ben Foster related by the El Paso Times. Ben Foster was noted for his shiftlessness. If it had not been for his wife, he would not have done a stroke of work on his little farm and garden. It was all she could do to get him to work, for he preferred to sit and read all day. One evening, after he had been reading French history with deep interest, he closed the book and said to his wife: "Do you know, Maria, what I'd 'a' done if I had been Napoleon?"

"Oh, yes, I know well enough," his wife responded. "You'd have settled right down on a farm in Corsica and let it run to ruin, while you grumbled about your hard luck."

*

WHEN preparing to boil a ham whole it is often desirable to soak it overnight, especially if it has been cured rather hard. Wash it thoroughly, then put in a large granite kettle, covering with cold water, and adding a white onion stuck with four cloves, two bay leaves, a blade of mace and two stalks of celery. Let soak overnight, then put the kettle over a moderate fire, where it will heat slowly and when it comes to a boil, let it boil 15 minutes for each pound of ham. Let it simmer gently, not boil hard. When cooked, remove from the water, carefully cut off the rind, brush with egg and then cover with bread crumbs. Put in the oven to brown this crust.

*

MANY a woman spoils her appearance by deciding that she can "get one more wear out of it," and then putting on some garment so soiled or wrinkled that it really calls for laundry or pressing iron before appearing in public. This is especially true in the Summer, when a plain linen gown, becomingly made, will put the farmer's daughter on a level with the city guest, as far as clothes are concerned. Wash fabrics are within the reach of every purse, but they must be fresh and clean. Here in the city we see dozens of girls every day who have not learned this lesson, and who are on the way to store or office in dresses that can only be described as "mussy." Many of them have no facilities for proper laundry work—while in the country, with clear air and pure water, labor is often a serious question. Every family must decide for itself how far its feminine members may go in wearing light-colored wash dresses. Dark-colored linens, with the removable white vestees and collars now so fashionable, save washing, and are suitable for town and visiting. They can often be worn a whole Summer without laundering, but they must be pressed frequently. Mercerized lawns and cotton foulards, black, dark blue, green or brown, make up prettily, either plain or figured. A person in mourning will find black dotted swiss cool and very nice-looking, but a plain slip of black mercerized lawn, sleeveless and low-necked, should be worn under it. But all these dark-colored cotton or linen dresses must be pressed, whenever wrinkled, or they do not look well, and really it is this care, in both laundering and pressing, that makes a woman look well-dressed, whether her clothes are costly or inexpensive.

The Rural Patterns.

When ordering send number and size of patterns desired. Price of each pattern 10 cents.

7493, Blouse or shirt waist. Cut in sizes 34 to 44 bust measure. Size 38 requires two yards of 36-inch material.

8274, Fancy blouse. Cut in sizes 34 to 40 bust measure. Size 38 requires 3⅝ yards of 27 or 36-inch material with ⅜ yard of net for vestee and sleeve frills. 7448, Semi-princesse gown. Cut in sizes 34 to 44 bust measure. Size 38 requires 5¼ yards of 36-inch material with ½ yard 27 inch wide for collar and cuffs. 8079, Ladies' three-piece skirt. Cut in sizes 22 to 32 waist measure. Size 26 requires 2⅝ yards of 36-inch material. 8292a, Ladies' two-piece skirt. Cut in sizes 22 to 32 waist measure. Size 26 requires 2⅝ yards of 27, 36 or 44-inch material with ⅝ yard 36 or 44 for insets.

8342, Plain blouse for misses and small women. Cut in sizes 16 and 18 years.

Size 16 requires 2⅛ yards of 36-inch material. 8244, Blouse for misses and small women. Cut in sizes 16 and 18 years. Size 16 requires 1⅞ yards of 36-inch material. 8334, Semi-princesse dress for misses and small women. Cut in sizes 16 and 18 years. Size 16 requires 3¼ yards of 36-inch material with two yards of 36-inch for sleeves and shirred chemisette. 8313, Girl's dress. Cut in sizes 4 to 8 years. Size 6 requires 2¼ yards of 27 or 36-inch material. 8287, Girl's combination undergarment. Cut in sizes 4, 6 and 8 years. Size 6 requires 1¾ yards of 36-inch material with 1½ yards of embroidery, two yards of insertion and 2¼ yards of edging.

Seen in New York Shops.

FLARING gauntlet cuffs of stiff white linen, four to six inches deep, with rolling collar to match are among the newer coat sets, appearing with the "Salamander" styles. The cuffs are fastened with links.

A combination vestee and collar with girdle attached is made of white pique with a fine rib. The collar is the usual rolling one, with a little design in hand embroidery in the corners, and the vestee is fastened with crochet ball buttons and loops. The belt attached at the waist line is one of those waistcoat girdles that come down below the waist with a cutaway effect, and is fastened with the ball buttons; it is about six inches deep in front, sloping up to about two inches in the back, where the ends are lapped over and finished with two buttons.

Among new artificial flowers are velvet begonias, which appear to be taking the place of gardenias. The large flat flowers of the tuberous begonias are imitated, but natural colors are not sought, and they are quite as often black, mauve or green as the tints of the natural flower. White velvet begonias on a black plush hat formed one fashionable model. It is likely that these begonias will be worn on Winter hats. At present, with women wearing all sorts of plush and velvet hats in June and July, one wonders whether straw will be the proper mode for December.

Some pretty middy blouses for young girls were made of white drill with collar, cuffs and tie of Roman stripes. Kilted skirts of white drill are suitable to wear with these blouses, though any colored skirt may be used.

Belts naturally accompany the coming change of figure, which will have a well-defined waist. For the present, broad crush girdles with a large flat bow in front or back are popular. The bow is the same width as the girdle, often six to eight inches, and it is more favored in front than at the back, though it should not be worn in front by a large woman.

Furriers are already showing the new styles in furs. They include fur capes of all sizes and shapes, but mostly longer in the back than the front. There are many cape-shaped collars. Fur coats are three-quarter length, falling in loose rippling folds, instead of being draped as they were last Winter. The popularity of muskrat is to continue.

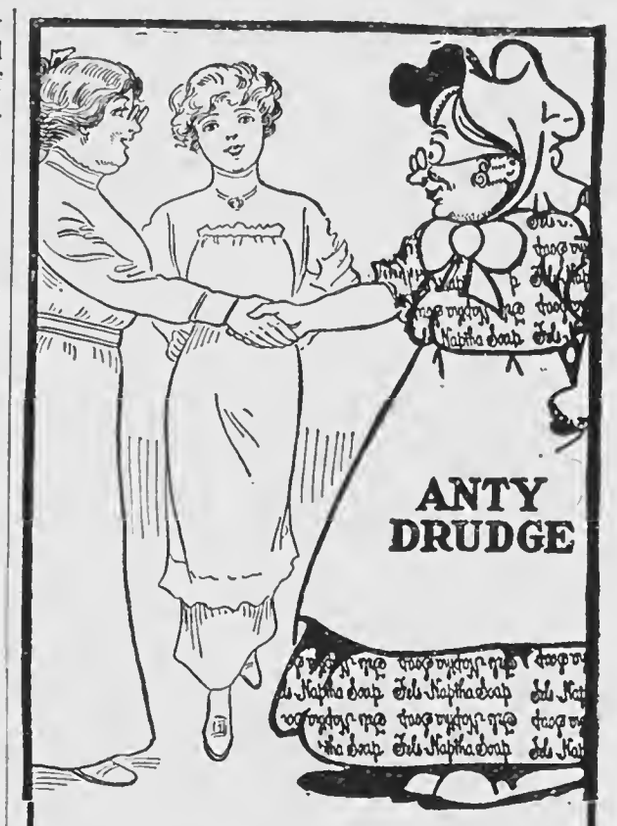
Some new basque costumes seen are strikingly like the jersey dresses of the early eighties. These consisted of kilted skirts and woven jersey basques that fitted without a wrinkle. The woven jersey has not yet appeared, but the basques have a decidedly jersey outline. These basques are made up at present chiefly with long tunic skirts, but pleated skirts are already appearing and are shown with kilt pleats attached to a tight-fitting yoke.

Separate round tunics of taffeta, edged with ruffles, are offered in black, white and several colors. They are intended to be worn over light Summer dresses, and as the fashion is now a waning one they are much reduced in price.

Skirt lengths of accordion pleating, with belt attached, are now offered in a variety of material, serge, taffeta, crepe de chine, etc. The pleating is of various depths, being intended for both tunics and skirts. Some of the tunic pleating is in points, the skirt length forming about four points.

White chinchilla coats are offered for seaside wear. They are medium length, full and loose, with belted back and deep patch pockets. A black velvet collar is the newest touch. They are pretty and becoming, but so quickly soiled that they are not at all practical.

Honey Gems.—Add one cup of honey gradually to one-half cup of butter, then the yolks of two eggs and half a cup of sour cream, two cups of flour with half a teaspoon of soda and a teaspoon of cream of tartar; stir well, flavor with lemon and fold in beaten whites of two eggs. Bake in gem pans in moderate oven.



Mrs. Goodsense—"Anty Drudge, my daughter has told me how kind you've been to her, and I'm glad to meet you. When I go back to the city I'm going to see that all my friends use Fels-Naptha Soap. Mary thinks it's the grandest thing she ever used. She says it's the greatest help she ever had for all kinds of work, and the directions are so easy to follow."

If you are one of the women who *don't* know about Fels-Naptha Soap and the easy, quick way it will do your work, you'd better lose no time trying it. You'll find that it's the best soap for *every* purpose that you ever used.

It works best in cool or lukewarm water, and does scrubbing, dish-washing, house-cleaning, even the weekly wash, in less than half the time and better than ever before.

Better buy it by the carton or box. Easy directions are on the Red and Green Wrapper.

Fels & Co., Philadelphia.

FELS-NAPTHA

Catering for a Small Income.

WHILE the writer has in mind the middle-aged woman retired on a small income, this article is not based upon any special allowance, but instead it has to do with economic business principles which may be applied to general purveying by the housewife in town, or on the farm—anywhere the small income exists, and that is everywhere. It has been stated that the greater number of failures in the United States—bankruptcy—have been among men who have become involved financially, not in business adventures, but by general indebtedness for the necessities and the superfluities of life—by living beyond their income, by overestimating their ability to pay. If this statement is true the American homemakers should become systematic and apply economic principles to purveying for themselves.

In order to handle a small income judiciously, a housewife must know just what she needs, when she needs it and how much. To know how much is to know how long a special amount will last. The small income means buying in small amounts, if the income is weekly, but if monthly or quarterly, larger amounts are possible. With a known amount of money for the weekly food supply, a housewife should on Saturday evening of each week make out a list, an itemized bill of actual necessities for the coming week, with estimated costs, the footing of which must be made to harmonize with the cash in hand for that purpose, either by omitting one or more items, or by reducing the amount of one or more, and this can be easily done with supplies that are weighed, measured or counted. There must be constant oversight of the food supply kept in stock, in order to prevent too many items coming together—too great a dearth during any one week. For instance, 25 pounds of bread flour will make all of the bread, pie and cake that two people should eat during one month. Wheat flour in this amount should be the largest single cash item for any one week; that is, all other stock commodities such as lard, rice, beans, etc., should be in just sufficient amounts to last from two to three weeks, leaving one week for flour and the usual weekly necessities, such as the daily supply of milk, fresh eggs, fruit, vegetables, meat and butter. When possible to get good new butter once a week, there is little economy in getting a larger amount and taking chances on the butter and its keeping qualities, for on the average one pound and a half a week will suffice two people.

As soon as a housewife knows how much she needs of any one food commodity for one week and its cost then she can adjust amounts so that the total costs will harmonize with her weekly allowance. In adjusting an estimated food supply to a money allowance there should always be a cash margin held in reserve for the unexpected. Food, the kind and amount, for an individual, is a matter for personal regulation, and each one is free to experiment, although three temperate meals a day are recommended. To understand the comparative value of foods is a help—it helps one to be resigned if not satisfied with a quart and a half of milk, knowing that it contains as much nutriment as one quart of oysters costing from 35 to 40 cents per quart, although it might not help one to eat oatmeal and beans forever. The small income and the normal appetite should go hand in hand; the appetite that relishes good homemade breads—the small all-over browned loaves of wheat bread, white and brown, also corn bread; milk, eggs, the cheaper but nutritious cuts of meats for kettle roasts and stews; baked and boiled potatoes, apples and dried prunes, peaches and apricots. Apricots cost from 15 to 20 cents a pound, but one pound will—soaked over night and stewed slowly—make four stewings for two people. The lasting qualities of a given amount of food must always be considered in connection with its cost.

Women living and eating alone are in danger of extremes—undereating and then overeating. They have not the inclination to cook for themselves as they would for others, and after skipping one or more meals, or taking just enough to satisfy the pressing demand, they later in the day eat two meals at one sitting—put two feet into one shoe, so to speak. To feed a pig or a calf in that way would result in a one-sided development—undersized. The lone woman with a small income is in danger of undereating through her desire to avoid indebtedness, if she invests her money blindly. She has no occasion to despair and think herself doomed to slow starvation—malnutritions—if she will only be consistent in her selections and combinations of food.

MEDORA CORBETT.

Tomato Catsup and Preserve.

WILL you give a reliable catsup recipe, and also different ways of pickling and preserving red plum and yellow pear tomatoes? MRS. B. C.

The following recipes are from the Rural Cook Book:

Tomato Catsup.—Pare one-half bushel tomatoes and cook until very soft, sift them, taking all the seeds out. Then cook until as thick as you desire the catsup and then add one quart vinegar, one-half pint salt, and the following spices: One tablespoonful each of cloves, ginger and cinnamon, two tablespoonfuls each of mustard, black pepper and allspice, and one-half teaspoonful cayenne pepper. Let it cook 10 minutes, then bottle and cork tight, no further sealing is needed as it will keep for years simply corked.

Tomato Catsup No. 2.—Wash and cut in pieces a half peck of ripe tomatoes. Cook in a porcelain-lined or granite iron preserving kettle till soft enough to put through a sieve, which will remove skins and seeds. To the pulp add two tablespoonfuls of salt, two tablespoonfuls pepper, one-half tablespoon allspice, one-half tablespoon cloves and one-half pint vinegar. Let the tomato cook for several hours before adding the spices and vinegar. Mix the salt and spices dry in a bowl, and blend well before putting into the tomato. Cook till quite thick and put in bottles. Store in a cool cellar.

Uncooked Tomato Catsup.—Peel and chop a peek of ripe tomatoes and hang in bag, to drain for 24 hours. Add to the drained tomato four bunches of celery (chopped fine) and one large cupful of chopped onion. Mix the three vegetables thoroughly and then add one-fourth cup of salt; one-fourth cup sugar; two tablespoonfuls mustard seed; two tablespoonfuls ground cinnamon; one teaspoonful ground allspice, and two large red peppers, chopped fine. Mix very thoroughly; cover with good cider vinegar, and put in self-sealing cans.

Egg Tomatoes in Sweet Pickle.—Pour scalding water over seven pounds of the egg tomatoes, let them stand for a moment, then remove the skin. Cover them with vinegar much diluted with water and let them stand twelve hours. Put one-half cupful of weak vinegar in the preserving kettle and add part of the tomatoes, then some sugar and any whole spices, such as ginger, allspice, cinnamon, cloves and mace, using these or even more varieties according to taste. Add more of the tomatoes, more sugar and more spices, alternating the layers thus until all the tomatoes and five pounds of sugar have been used. Cook very gently, stirring just enough to prevent scorching without breaking the tomatoes. When these are quite clear and transparent, remove them carefully and boil down the syrup. When the syrup is thick strain it and add the tomatoes. Boil up once and pour into pint jars to be sealed at once.

Tomato Jam.—Select sound, ripe fruit and peel and quarter them. Then put them into the preserving kettle with an equal weight of loaf sugar, the strained juice and rind of a lemon for every four pounds of the fruit, and a little powdered ginger. Cook the mixture slowly until it jellies when tried on a spoon. Turn into jars and cover.

Tomato Marmalade.—Remove the skin from four quarts of ripe tomatoes and slice. Cut six large lemons in halves, lengthwise, and slice very thin. Seed one cup of raisins. Put the tomatoes, raisins and lemons into a preserving kettle, in layers, alternating with four pounds of granulated sugar. Cook one hour on the front of stove. Then set the kettle back, and allow contents to simmer until it is of the consistency of marmalade. Put up, while hot, as jelly. This recipe makes about two and one-half quarts. When properly prepared no one article will be recognizable. The small yellow tomatoes are nice for such use.

Tomato Marmalade No. 2.—For every two pounds of the tomatoes allow two pounds of sugar and the juice and grated rind of one lemon. Pour scalding water over the tomatoes to loosen the skins. After removing the skin, mix the tomatoes with the sugar and boil slowly for one hour, stirring and skimming frequently. At the end of that time add the lemon juice and rind and cook another hour or until the whole is a thick, smooth mass.

Tomato Mock-Orange Marmalade.—Scald and peel large-sized yellow tomatoes. Cut downward over each seed section, press open and remove all seeds with the thumb, leaving the pulp comparatively whole. To two parts of the prepared tomatoes allow one part of oranges, slicing thinly. Cover all with an equal quantity of sugar and let stand over night. In the morning pour off syrup and cook down about half, add the tomatoes and oranges and cook until the orange skins are transparent. Seal in jelly glasses. This is an original recipe, and is a delightful substitute for the genuine orange marmalade, though much cheaper.

Books for Boys.

THE Board of Education of this city has given out a list of books which, they say "no boy from 12 to 14 will go to sleep over." This list will no doubt be interesting to those who wish to select reading for boys. It is as follows:

1. Kipling—"Captains Courageous."
2. Moffett—"Careers of Danger and Daring."
3. Pyle—"Jack Ballister's Fortunes."
4. Bostock—"Training of Wild Animals."
5. "Famous Adventures and Prison Escapes of the Civil War."
6. Hill—"Fighting a Fire."
7. L. G. T.—"Three Years Behind the Guns."
8. Altsheler—"Young Trailers."
9. Barbour—"For the Honor of the School."
10. Barnes—"Yankee Ships and Yankee Sailors."
11. Brady—"Border Fights and Border Fighters."
12. Brooks, E. S.—"Master of Strong Hearts."
13. Carruth—"Track's End."
14. Kieffer—"Recollections of a Drummer Boy."
15. London—"Call of the Wild."
16. Macfarlane—"Redney McGraw."
17. Masefield—"Jim Davis."
18. Munroe—"Campmates."
19. Poe—"Gold Bug."
20. Stevenson—"Treasure Island."
21. Stockton—"Buccaneers and Pirates of Our Coast."
22. Stoddard—"Battle of New York."
23. Tomlinson—"Search for Andrew Field."
24. Twain—"Huckleberry Finn."
25. Verne—"Twenty Thousand Leagues Under the Sea."

It will be noted that Alger, Trowbridge, Henty and other who still thrill boy readers are not represented in this list. Our own favorites in this list are No. 1, No. 19, and No. 20.

To Darken the Stove.

TO darken the top of a cook stove form a piece of clean old cotton cloth into a pad, wet, squeeze and apply any yellow laundry soap and rub the top until the pad becomes too hot, then dip the soap into water, rub the cloth and the stove, and continue the process. If a stove is soaped twice a day or even once, just after dinner, it will be kept in a presentable condition during the afternoon. The soapy odor may be overcome by placing a pinch of ground coffee on the stove top. There is an old saying that a new stove rubbed daily with a soaped cloth will never need blackening on the top. M. C.

GREEN TOMATOE PICKLES.—Gather full grown green tomatoes; make a strong ginger tea (root is strongest) into which drop your fruit, scald well; to each pound tomatoes take one-half pound sugar, one-half pint vinegar, make a syrup of this and put tomatoes in, cook until perfectly clear, add cinnamon, mace and white ginger, cover well with syrup and tie up closely. Cut stems out so juice will penetrate. MRS. D. S. R.

Spear's Special

"Get Acquainted" Offer

½ Price

Metal Bed, Spring, Mattress & Pillows Complete

ONLY $8.85

Regular Price, $17.75

Sent on 30 Days' Free Trial

Offer Good until Nov. 1st.

"A beautiful iron bed with graceful, continuous posts. Measures 4 ft. 6 in. wide; may be had in vernis martin or white enamel finish. Spring has rust proof steel fabric securely attached to heavy steel frame. Mattress has felt top, weighs 50 pounds and is covered with good striped ticking. Pillows filled with select feathers, weigh three pounds each. Can you think of a bigger or better value?

Complete Outfit Shipped on 30 days' free trial. Order No. D351. Price $8.85. Terms, $1.50 cash with order, balance payable 75c monthly.

"I'm making this great offer—slashing the price *right in half*—just to get acquainted with you who love your home—just to SHOW you how I've *taken the bars down on credit* and prove to you what remarkable BARGAINS I can give you in everything for the home. But I can only afford to make this ½ Price offer until Nov. 1st. So take advantage of this big, special bargain *now*. And remember

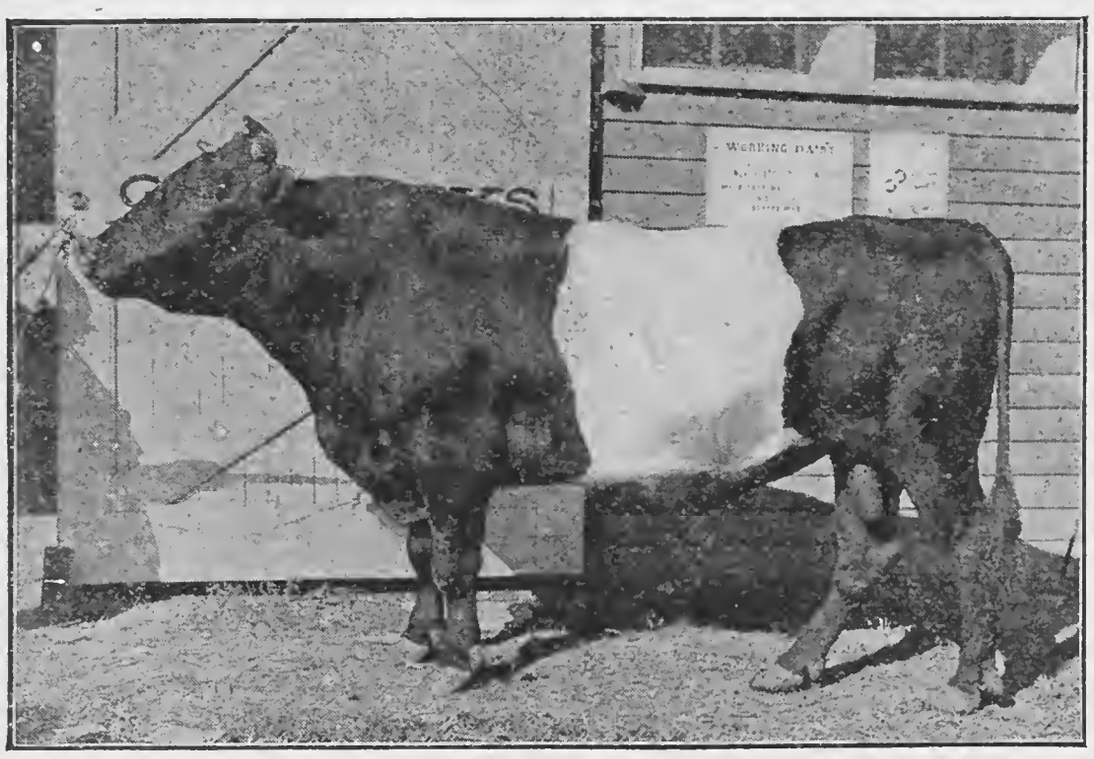
Live Stock and Dairy

RAISING CALVES WITHOUT SKIM-MILK.

IN those regions where market milk is produced, it is usually more profitable to sell it to a shipping station, than to dispose of it in any other way, unless it can be retailed. Even when otherwise disposed of in the Summer it is frequently shipped in the Winter. In such sections, therefore, the dairyman seldom has skim-milk when he wants it to raise calves. The result of this condition was, for a long time, to discourage the raising of calves in these sections. Until recently the price of cows was low anyway, and a good judge could pick out good cows as cheap as he could raise them. Conditions have now changed. Good grade cows now sell at from $75 to $100 in this neighborhood, yearlings at $25 or $30 and so on. The result has been so to stimulate the raising of calves, that it



DUTCH BELTED BULL.

is now difficult to buy a good heifer calf to raise.

As there is no skim-milk to be had, there have been numerous letters to the farm papers, inquiring as to methods of raising calves on substitutes. I have been through a good many methods, and have settled on one as satisfactory. As I have never seen this method given in any book, bulletin or article, I will give it here. The first calf I ever raised, was raised on the waste from the manufacture of powdered or dried milk, which is simply dried skim-milk. This method was successful, but owing to improved processes, there is now none of this waste to be had, and the dried milk itself is too expensive to use.

The next thing I tried was commercial calf meal. I had fair success with the two kinds I used, but they are expensive, and a great bother to prepare properly, and the results left considerable to be desired. One of these calf meals is a good deal better than the other, but a mixture of red dog, ground oats, with the hulls screened out, or flour middlings, and old process oil meal, is still better and much cheaper. These calf meals are scalded and fed in the form of a gruel.

The method which I now use, and which I prefer to all others is as follows: The calf is allowed to suck the first milk from the cow, and then taught to drink. They should never suck but once, as the longer they are allowed to suck, the harder they are to teach. After that they get one quart of milk mixed with one quart of cold water, just as it comes from the tank, twice a day. I like to let them run in a stall, but they may be tied if necessary. After a week hay and grain are kept before them. After each feeding, a little grain is put into their mouths, and in a surprisingly short time they are eating like old cows. If desired, the amount of milk fed may be increased from time to time, but it is not necessary. In a month or so, when the calf is growing well, and eating plenty of hay and grain, the milk can be gradually withdrawn. It is well to increase the amount of water given before this time, as the dry fodder consumed necessitates it.

Most people, when hearing of this method for the first time, imagine that the calves are starving, but if carefully fed, they are soon making rapid growth. The man from whom I learned the method is uniformly successful, as are others who practice the same methods. I have known him to sell calves that he started to raise, for veal at top notch prices. For grain, I fed straight bran last year. This year I am feeding a mixture of bran and ground oats, 100 pounds each, and old process oil meal 40 pounds. Bran is valuable for its bone making materials. Red dog and flour middlings are also good. Fall calves raised by this method, are ready to go out to grass in the Spring, and require no more attention except an occasional salting as long as the pasture is good. If the grass gets short they should receive additional feed of some kind, as it is poor policy to let them stop growing at any time. There are two precautions to be observed in starting calves by any method: First, absolute cleanliness of utensils, and second, care in weighing or measuring out the rations. If the ration is suddenly increased, the calf is likely to start scouring, which is always a setback. If it is desired to feed skim-milk, it should be first substituted for the water, and then gradually for the whole milk.

Jefferson Co., N. Y. A. H. DE GRAFF.

FEEDING CALVES SOUR MILK.

THE U. S. Department of Agriculture fed sour milk to 22 calves, and claims that in no case did it cause digestive disturbance, even when the calves were only a few days old, and asserts that the common idea that sour milk causes scours, is quite unfounded. It seems saucy to contradict such high authority, but it should be done. The common idea is true as the gospel. The Department of Agriculture is amazingly wrong. For 50 years I have taught a dozen calves, every year, to drink milk, and fed them personally afterwards with milk until they were old enough to do without it. A calf only a few days old will not *drink* sour milk, and ought not to drink it if it would. When three weeks old a small quantity—say two quarts at a feed—can be safely given continuously without fetching on the scours. Even sweet skim-milk will cause the scours if fed all they will drink. About five quarts at a mess, is as much as should be given. They should have all the water they will drink, especially after they have learned to eat wheat middlings, and nibble hay. Fresh buttermilk is relished by calves, and is safer to feed than sour skim-milk. The Department did not tell us how much sour milk was fed to each calf; how many times a day the calves were fed; and how long the experiment was continued.

Pennsylvania. J. W. INGHAM.

THE DUTCH BELTED BREED.

THE picture shows a Dutch Belted bull of good conformation. This breed was originated in Holland about 250 years ago, the peculiar belt about the body being the result of scientific breeding. The cows weigh from 900 to 1,250 pounds, and bulls from 1,500 to 2,000. In addition to their beauty the Dutch Belted cattle are creditable dairy and beef producers.

WISCONSIN COW-TESTING ASSOCIATION.

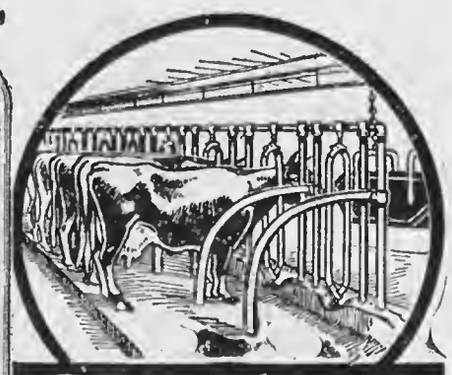
YOU ask the proportion of unprofitable cows in the average herd. That would be a very difficult thing to say, unless I was finishing the year, as this would enable me to say more clearly the exact number. But I do think without exaggerating a bit, out of the 485 cows in my association that two out of every 20 are not worth the feed and care they receive, and this association is classed as having some very fine herds, as this is its second year of work. The association has a large variety of breeds. The largest in number are the Guernseys, second Holsteins, third native and last the Jerseys. The best stand in butterfat I have obtained was from a herd of 10 during the month of May; they averaged 43.3 pounds of butterfat. From the whole 485 cows for the month of May the average amounts to 23 pounds of butterfat each. R. C. F.

Amherst Jct., Wis.

I COULD not tell very much about how many or what per cent. unprofitable cows I am testing now until the end of the year. In some herds I know all will make a good profit, while in other herds one-half are boarders. I should say the average would be three boarders to every herd of 12 cows. A part of my association was testing last year and weeded out a great many. But they also studied feeding more than ever, and fed more. This year the largest percentage of unprofitable cows are in the new part of the association, where testing was not done before. The largest record I have for one cow one month is 82.5 pounds fat. The average run is about 30 pounds fat. This is only an estimate, as I have not averaged it exactly to the pound. Half of my association, as I stated above, tested last year, or my average would be about 25 pounds fat per month. R. F. A.

Waupaca, Wis.

LITTLE Bertie had just been stung by a nettle. "Mother," he asked, "if a bee settled on a nettle, would the bee sting the nettle or would the nettle sting the bee?"—Melbourne Australasian.



LOUDEN

STALLS and STANCHIONS

The Clean-Cut Simplicity of Louden Stalls and Stanchions in design and construction; their absolute freedom from dirt-gathering cracks, crevices, corners or attachments, make them the **only really sanitary barn equipment.**

The Superior Flexibility of the Louden Stanchion permits the cow to lie down or rise without the dangerous straining common to the more rigid type. The Louden Stanchion (all steel or wood-lined) is an absolutely safe and comfortable stanchion.

Louden Stalls and Stanchions are built of the finest, high-carbon tubular steel and are exceptionally strong, easily installed and cost no more than wood.

We also manufacture Feed and Litter Carriers, Spring-balanced Mangers and Manger Partitions, Bird-proof Barn Door Hangers, Hay Tools, Power Hoists; Calf, Bull, Cow and Pig Pens, Window Ventilators, Etc.

Write us for Free Illustrated Catalogs, or see your dealer. We can be of service to you in planning your new barn. Our barn experts will give you FREE sketches and suggestions that will be of value. Write us.

BEEF CATTLE FOR NEW JERSEY.

WE are in a section where it does not pay to produce milk or butter and have been thinking of raising prime beef cattle, such as are raised in the western part of the country to supply the cities. Our plan is to let the calf run with the cow continually until it weans itself, and in every way strive to get the quickest growth into beef possible. Will you give me the names of some of the largest breeds of beef cattle and an approximate estimate of the weights they attain at one, two and three years? Would it be a good plan to breed a bull of these large cattle to our cows, which are grade Holstein? A. C. K.

North Branch, N. J.

It would not be good practice for A. C. K. to breed his dairy cattle, which are grade Holsteins to a bull representative of one of the beef breeds, namely Shorthorn, Aberdeen-Angus or Hereford. In the first place such progeny would have neither milk-making nor beef-making propensities, and would be identified as cross-breds, and in all probability would bring no more for beef purposes than the progeny of a dairy cow in good flesh. It is doubtful whether beef production would be profitable in areas where dairy cattle properly handled have failed to show a profit. A dairy cow is a far more economical unit for converting food products into readily salable products, and it will be noted that in sections in the Middle West where beef production has engaged extensive development, that the dairy cow is pushing herself in, and in some cases replacing the beef animal. The great difficulty experienced by those who have endeavored to produce beef cattle in the East has been to persuade the local dealers to recognize its value. A very small percentage of the butchers in the East actually slaughter animals, preferring buying them on the block rather than on the hoof. It is not unusual to find localities where the buyers will pay no more for a prime steer than they will for a fat dairy cow, and naturally one cannot afford to supply this sort of a market. It is true that there is less labor involved in caring for beef animals than for the dairy cow, but it is necessary to have a silo, and to grow corn extensively even though the beef animals are fed. In the Western States where beef cattle are raised extensively, the silo is rapidly coming into use, and it is admitted quite generally, I believe, that silage materially reduces the cost of producing beef. A number of New Jersey farmers during the past two years have endeavored to bring on from the West market steers as feeders, but when the cost of transportation is considered, together with the lack of market facilities, it is doubtful whether market prices, for the grain consumed were received.

The chief beef breeds may be identified as the Short-horn, Aberdeen-Angus, Hereford and Galloway. The bulk of the feeders are marketed under two years of age. Choice to prime steers weighing from 1,500 to 1,600 pounds were quoted at the Chicago markets last week as bringing from nine to 10 cents per pound. The bulk of the yearling past stuff is marketed at a weight of from 1,250 pounds to 1,300 pounds, and the choicest of these at the Chicago markets are now selling for about 10 cents per pound. Under good conditions, and if liberally fed, Short-horn two-year-olds should be marketed when weighing from 1,250 to 1,500 pounds, and it is necessary to keep them growing from birth to maturity without marking time.

In my judgment I believe that the possibilities in the Eastern States today are in the marketing of cream, and the keeping of the skim-milk on the farm and feeding same to swine. If corn and Alfalfa can be grown successfully, it would seem that the dairy cow, supplemented by the fat hog, would be a sure source of profit to the Eastern farmer rather than the raising of beef cattle of any type or breed. F. C. MINKLER.

Green Feed for Horses.

ON the whole we have not found green feeds very satisfactory for horses. In Europe a great deal of green feed is fed but they can do so much better there on account of climatic conditions. However we have fed quite successfully some sugar cane and Alfalfa as soon as it was cut. We would not recommend even too much of this as it is liable to colic the animal. TAYLOR & JONES.

Illinois.

Paralysis.

WHAT is wrong with my sow? She weighs between 200 and 300 pounds. She had eight pigs, and the same day they were five weeks old she went down with hind part of body, is not able to stand on hind legs at all. I can help her so she gets on her front feet but is seems to cause her very much pain. She will drink out of bucket after she is on her front feet. I fed her a slop of bran middlings and hominy feed all she wanted. H. A. L.

This attacks sows that have been overfed and underexercised and that come from similarly pampered stock. Overfeeding on corn is most likely to produce the tendency to the trouble and it is brought on by the care and drain of nursing pigs. The pigs should be weaned at once; then feed the sow on light slop, adding 10 per cent. digester tankage. Also allow green feed and roots. If she improves so that she can walk turn her out on grass. The disease does not attack sows that are from naturally fed and exercised stock and that are themselves fed mixed rations from birth and made to run out daily. A. S. A.

Seedy Toe.

WHAT is dry canker and what causes it? We have a mare whose left fore foot is infected. The hoof has a cavity nearly to the bone, leaves the toe just a thin shell. It has been scraped or cut out and disinfected by a licensed veterinarian who tells us she will not be able to wear a shoe in two months. Will standing on the barn floor or wearing shoes too long before resetting cause the trouble, or is it infection or improper shoeing? She is a healthy little animal otherwise. Does not have any hard work, just light driving. Will she get over this trouble and not be lame? She is 19 years old this Summer and never been bred. Could we breed her with safety to her?

New York. E. E. F.

We do not recognize any condition of the hoof by the term "dry canker." The condition present is known as "seedy toe," and commonly is induced by the pressure of a tight toe clip; or it may come from failure to have the shoes reset once a month, or be due to a bruise upon the wall of the toe. Cut away all loose and under-run horn of sole and wall; then scrape out all powdery material and plug the cavity with oakum saturated in a mixture of one part each of turpentine and coal tar disinfectant and six parts of melted pine tar. Renew the dressing every three days. A bar shoe may be put on and held in place by means of side clips, instead of a toe clip. It would not be wise to have the old mare bred. A. S. A.

SPECIAL NOTICE TO EXHIBITORS

At the suggestion of the State Department of Agriculture all premiums offered in the Swine Department are withdrawn for the Poughkeepsie Fair to be held September 7-8-9-10-11 and 12, 1914.

DAIRY CATTLE

Purebred Registered Jersey Cows and Calves FOR SALE
B. G. WELLS, R. D. 41, Wyalusing, Pa.

FOR PRODUCTION—BREED UP, NOT DOWN—Registered Jersey bull calves, only, from producing dams and highest type sires. R. F. SHANNON, 603 Renshaw Bldg., Pittsburgh, Pa.

A Good Jersey Bull with Grade Cows

is a start in the right direction. If you cannot have all full-bloods, you can at least have a sire with known lines of breeding. The sire is the greatest factor in enlarging the producing value of your herd.

The great milkers and great dairy herds are not the result of accidents. Breeding to a thoroughbred bull should be your first move.

This Club has neither cows, bulls nor calves for sale. It is maintained solely in the interest of Jersey breeders. We shall be glad to send you helpful facts and information. If you are a Jersey breeder, membership in this Club will be valuable to you. If interested, please address

Heart's Delight Farm DUTCHLAND COLANTHA SIR CHANGELING
Born August 17th, 1908
Sire: Colantha Johanna Lad—62 A R O daughters
Dam: Changeling (29.23 lbs. butter in 7 days.)
Average of dam and sire's dam 32.23 lbs. butter in 7 days. Will sell or exchange him for pure bred heifers or grade dairy cows. Our reason for selling is we have a number of his daughters.
W. H. MINER, CHAZY, NEW YORK

East River Grade Holstein Cows For Sale
100 cows served to calve in August, September and October, all served to registered bulls. STRICTLY DAIRY TYPE AND GUARANTEED. 60 yearling heifers. 40 two-year old heifers all sired by pure blooded bulls from high producing dams. 10 extra well-bred registered bulls, PONTIAC BREEDING, from A. R. O. DAMS. If you are looking for extra good dairy cows, visit the EAST RIVER HOLSTEINS. Special price for the next 30 days. WE TUBERCULIN TEST. JOHN B. WEBSTER, Dept. Y, Cortland, N. Y. Bell Phone 14, F.5.

HIGH GRADE
HOLSTEINS
100 cows due to freshen in Sept. and Oct.
100 fresh cows and springers.
PRICE, $75 to $100.00 EACH
All large, well bred, nicely marked and heavy milkers. 100 2-year-old heifers due to freshen this Fall, and all in calf by registered bulls. You can pay more but you can't buy better.
F. P. SAUNDERS & SON, Cortland, N. Y.
Office, 50 Clinton Ave.

Purebred Registered
HOLSTEIN CATTLE

According to figures compiled by the department of animal husbandry of Illinois University, a cow must produce 4,000 pounds of milk and 160 pounds of fat a year to pay for feed and labor. Every 1,000 pounds above this brings a yearly profit of $10. Thus a 5,000 pound cow earns $10 a year, an 8,000 pound cow earns $40, but when production reaches 10,000 pounds the profit is $63.

Systematic investigation confirms the wisdom of those who have taken up the Holstein-Friesian breed.

Each weighs more than a ton. Sons and daughters of each to be seen on the farm. A rare opportunity to purchase the best. Ones that can win in any show ring. Also 2-year stallions.
PIEDMONT FARMS, F. W. Okie, Owner, Marshall, Va.

Day after Day, Year after Year, PRODUCTION COUNTS
It is not what a cow can produce in 7, 14, or 30 days, even in a year that determines her value to the farmer, it is what she can do in a lifetime.
Brown Swiss Cows rank high in average production and are regular and persistent breeders and producers. Year in, year out, they make good records and raise good calves without any coaxing or pampering. If interested, we will send you an illustrated booklet.
The Brown Swiss Cattle Association
IRA INMAN, Secretary BELOIT, WISCONSIN

Carbolic Acid and Contagious Abortion.

IN what proportion should I feed crude carbolic acid in salt to prevent abortion in cattle? W. M. H.

Contagious abortion in cows is not treated by feeding crude carbolic acid with salt, but by administering carbolic acid in solution with water, usually of four per cent. strength, mixed with the cow's feed. The quantity used varies with the length of time that the cow has been in calf and with the stage of the treatment. It is best prescribed by a competent veterinarian who can have the cows taking it under observation.

M. B. D.

The Fat Cow and the Milk.

AT the present time, it seems to be pretty generally conceded that a cow may be fattened while she is dry, so that when she freshens and begins to secrete milk, she will use for this purpose not only the nutrients in her feed, but the fat from her body, the result being that she not only gives a large amount of milk, but it is often considerably higher in fat percentage than it is later on, the length of time during which this condition prevails seldom being over a month or six weeks. I know of no data that goes to show that a cow will give any richer milk merely because she is plump or fat than she will if she is thin, provided of course that the cow is not changing in condition; in other words, while a fat cow is becoming poor, she is likely to give not only more but richer milk, but a cow that is in a plump condition and continues so is not likely to give richer milk than she would if she were in a thinner condition.

Ithaca, N. Y. H. H. W.

Effects of Heavy Feeding.

MR. MORSE'S letter on fat milk from fat cows, on page 871, and your inquiry in next issue moves me to give my experience. Twelve years ago I drew milk to a large butter factory and some of us believed as Mr. Morse does. At the Spring factory meeting we put up a fight and got all the milk taken on butterfat test. The theory did not work out. The best fed cattle were the lowest in fat for the entire year. I milked 30 cows fresh in March and April, common scrub cows, as every dairy in the factory at that time was the same. My cows were well fed and freshened in a good healthy condition and as they decreased in quantity they increased in butterfat until in September they were turned into after feed and fed sweet corn ears, and all milk flow increased 150 pounds per day, butterfat decreasing in proportion.

As to the poor cows, the dairy that gave the largest fat test in the factory was 22 cows wintered on straw and beaver meadow hay and were in a disgraceful condition, still his check was nearly as large as mine, and this proved true for the four years I was a patron of the factory. The poorest fed cows gave the least milk and most fat.

Another thing I want to speak about is that our experts are advising too heavy feeding. It might work out right in expert hands, but here hundreds of our best cows are going to market every year from the effects of too much heavy feed. I see them every Saturday, udder gone, barren and fed out and struck with death. I wonder what they do with them down at New York? I am a dairy farmer and wish I could hear more from my dairy brothers. B. B.

Oneida Co., N. Y.

Octagonal Silo.

I HAVE been reading inquiries about building octagonal silos. I built one six years ago and have helped build a number since. I take 2x8 inch lumber and make an octagonal hoop, spiking the corners with 20-penny nails. I set these hoops two feet apart as high as I want silo. On the inside of these I use two thickness of inch boards, nailing them up and down, being careful to lap cracks with second thickness of boards. For the doors I leave an opening two feet wide the entire length of silo, which makes almost a continuous opening, with the exception of where hoops go around. I make the doors two feet square, so they will just fit from one hoop to the other. On the outside of these hoops most of them use matched timber ceiling up and down, and there are a number that have no protection on outside. I have built some that I furred up and down on hoops with 1½x4 inch strips and clapboarded outside, which makes a very neat job.

Cherry Valley, N. Y. A. H. B.

Round Silo.

ON page 872 L. Q. P. inquires about using 2x8x7 feet long, circled out to build up a circular frame for silo. Some valid objections were given in answer by John Gould. There are others. Eight pieces seven feet long would reach around a 17 foot circle and he would want pieces sawed to have a least four inches in narrowest place in circle. Such a circle would require 12-inch boards instead of eight-inches. Just think of the waste cut out of 12-inch stock. The inside sheathing will shrink and he cannot take up this shrinkage as is done with hoops on a round silo. He should not use creosote on inside of silo as the steaming silage will absorb it and the cows' stomach will be burned and their kidneys put in bad condition. G. B.

Massachusetts.

Raising Pheasants; Forest Land.

I AM raising a few pheasants. What is the best food for them when young and older? 2 Some one has told me that forest land in New York State is exempt from taxation. We use ours for forest puproses, i.e., stove wood and occasionally cutting for timber. Can it be exempt? If so, what are the conditions attached, if any? Does Connecticut have such a law? S. M. P.

Port Chester, N. Y.

1. Pheasants are very like turkeys in their habits, and I should expect that suitable food for one would be all right for the other. The superintendent of the New York State Game Farm at Sherbourne, Chenango Co., N. Y., could probably give more definite information on the subject.

2. Some classes of forest land in New York State may be exempt from taxation and others may have the tax reduced. Woodlots, under certain conditions, are to be assessed not higher than similar land bearing no trees, and in no case more than $10 per acre. To obtain this special classification and taxation the land must be:

Not more than 50 acres.

Not nearer than 20 miles to a city of the first class.

Not nearer than 10 miles to a city of the second class.

Not nearer than five miles to a city of the third class.

Not nearer than one mile to an incorporated village.

The owner must make application in suitable form to the Conservation Commission to have the land examined and classified.

No grazing or pasturage must be permitted on the land.

None of the timber may be cut except for firewood or domestic use on the farm unless 30 days' notice is given the Conservation Commission, and then only trees marked by the agent of the Commission may be taken. Before any timber which has been cut *except for firewood or domestic use* may be removed the owner must pay the tax collector of his town five per cent. of its stumpage value. This stumpage value is to be determined by the assessors. A. C. W.

AILING ANIMALS.

Leaking Teats.

I HAVE 15 cows, and about five of them lose milk before milking time. Is there any way to stop this?

New Jersey. C. E. S.

After milking soak the leaky teats in strong alum water. Try this for a time and if it does not suffice, paint the ends of the teas with flexible collodion, or put on wide, weak rubber bands, or tapes. A. S. A.

Disease of Cattle.

WE have lost five head of cattle in a short time. They get sick at once, get stiff and not one got over it. The one that was sick the longest died in just two days from the time it got sick. The quickest was Saturday last; it was well in the afternoon at three o'clock, with the rest of the cattle, and at 7.30 is dead. They all act the same way. We opened some and found nothing wrong with them. What is the trouble?

Pennsylvania. S. S. F.

You do not give sufficient details upon which to base a confident opinion. We should be told the age of the cattle and how fed. If they are under two years old they probably die of blackleg, which might be vaccinated against. In that disease swellings form on the neck or quarters and give out a crackling sound when handled. Anthrax kills cattle of any age. Blood issues from the natural orifices of the body after death. A graduate veterinarian should be employed at once to make an investigation. A. S. A.

Kittens With Distemper.

WE are having very bad luck with our kittens. When they are about two months old they begin to have sore eyes. They get red and run, stick shut and are all scabby. The kittens get thin and after a while die. Will you tell me what is the matter with them and what to do for them? G. B. R.

The kittens no doubt die of distemper, which may be vaccinated against, if you can employ qualified veterinarian. Otherwise it proves fatal in many cases. Wash the eyes twice daily with a 10 per cent. solution of boric acid. Put a pinch of sulphur in the milk or water. If fever runs high a drop of tincture of aconite may be added to a saucerful of water or milk. Give the next kittens a new sleeping place. A. S. A.

Garget.

I have a Jersey cow six years old, which was taken with milk fever about three days after she became fresh. I sent for a veterinary who gave her the air treatment. She seemed to get better at once, and was ready to eat in about a half day, but it was about two days before she could get up. Then after being around for about a day she got so that she would not eat. The veterinary then gave her nux vomica, and told me to bathe her udder with hot water. Before this we kept the udder well pumped with air, changing quite often. I have bathed the udder about six or eight times a day and milked her morning and night for about 10 days, and it is pretty well softened up except one hind quarter, which has a hard lump running up the back. She gives no milk at all but a yellowish, watery fluid and some thick yellow substance, which is quite tough and at first came quite freely in large chunks. She is now in good condition, except the udder, which does not seem to be coming back to milk. Do you think anything more can be done for her? B. H. P.

Ohio.

Only one inflation with sterilized air is necessary in a majority of cases of milk fever, and great care has to be taken to prevent infection by sterilization of the milking tube and injection syringe. Infection appears to have ruined the udder for dairying, and you might as well sell the cow to the butcher or fatten her for slaughter. A. S. A.

Skin Disease.

Will you inform me as to the proper course to follow to rid brood sow and two-months pigs of scurvy? H. B.

New York.

You should describe the symptoms of what you call "scurvy," as that is not a recognized disease of swine. Meanwhile dip and scrub them with a 1-100 solution of coal tar dip, applied hot. Then rub in flowers of sulphur. Repeat the treatment as often as found necessary. We take it for granted that a skin disease is present. A. S. A.

Saddle Sores.

I have a nice riding and driving horse that has saddle galls on her back. What should I put on them to cure them?

Lexington, Va. D. A. G.

In such cases it is common to find patches of dead horny skin in the sores. These are called "sitfasts" and have to be cut out before permanent healing will take place. Apply twice daily a lotion compound of one ounce of sugar of lead and six drams of dried sulphate zinc shaken up in a pint of soft water. Label the bottle "poison." If the sores do not heal readily stop using the lotion and apply three times a day an ointment composed of one dram each of tannic acid, boric acid and iodoform rubbed up in one ounce of lard. See that the saddle fits properly and that the padding is level and smooth. Keep it clean. Also use a clean saddle cloth. A. S. A.

Red Water.

Red water in cattle is very prevalent here. Can you give an outline of treatment and if anything is known as to cause of the disease? A common belief here is that it comes from cattle eating ferns (brakes) and the dust from the ferns in hay. Some lay the cause to feeding too many rutabagas and the authorities seem to be as much at variance as anyone else. B. E. M.

This is a vexed question, and one for the veterinarians of your State agricultural experiment station to handle. Write to them for information, as they no doubt have given it attention. Rutabagas do not cause red water; neither have we seen it caused by the eating of ferns (brake or bracken). It is more likely to be due to acrid matters in wild pasture in timber or low lands. It often is due to heated oats. Tablespoonful doses of alum given two or three times a day in water may be tried; or dram doses of dried sulphate of iron, or iodide of potash may be substituted, but not for cows in calf. Remove such causes as we have suggested. A. S. A.

Sirenia Oil Drives Away Flies

Flies Kill Profits

Sirenia Oil—analyzed and endorsed by the Westfield Board of Health—is made of pure oils and is harmless for all external applications. It will not blister or cause the hair to fall off.

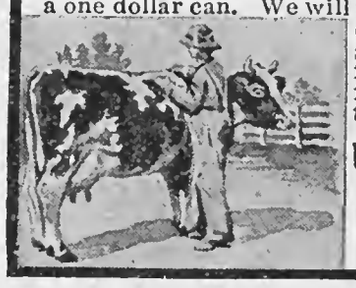
Sirenia Oil

is applied with a cloth, not a sprayer. It drives flies from cattle and horses, fleas from hogs and dogs, flee from poultry and ticks from sheep.

It heals sores and scratches.

Money Back If Not Satisfied

Your dealer should have Sirenia Oil—if he hasn't, send us his name and one dollar for a one dollar can. We will prepay delivery charges and guarantee satisfaction. Write for results obtained by users.



United States Whip Co.

Westfield, Mass.

CREONOID

Protects the Cows

Spray your cows with Creonoid before they go to pasture and they will not be tormented, will feed better and produce more milk.

Spray them again before milking so that the flies will not harass them and they will stand quietly.

To secure more eggs, use Creonoid and get rid of lice in the hen-house.

Powerful. Low-priced.

The Henyard.

THE EGG-LAYING CONTEST.

THE thirty-eighth week, ending July 24, shows a drop of 148 in egg production, as compared with the previous week. At this time of the year the price of eggs begins to rise because fewer eggs are sent to market, the drop in egg production being practically universal. As was predicted last week the "sour milk" pen of White Leghorns from Storrs Agricultural Station has passed Tom Barron's White Wyandottes, and is now at the head of the procession. The totals are 1,592 for the Storrs Leghorns, and 1,591 for Barron's Wyandottes. Francis F. Lincoln's White Leghorns are third with a total of 1,564. All the high scores are made by the White Leghorns again this week. Tom Barron's pen leads with a record of 57. Thomas W. Moore's pen is second with a score of 56. Chas. Heigl's pen ties with Geo. A. Cosgrove's for third place with scores of 54 each. Pen No. 42, the "sour milk" pen from Storrs, laid 53. Marwood Poultry Farm ties with Chas. N. St. John's pen for fifth place, with scores of 52 each. P. G. Platt's pen laid 51, and A. B. Hall's pen laid 50. The highest number laid by any pen outside of White Leghorns was 47, laid by Tom Barron's White Wyandottes.

The actual progress being made in increasing egg production is illustrated by the fact that at the Thorndale contest, where there are but five birds in a pen, same as there were in the first two years at Storrs, the gain in egg production up to the thirty-seventh week was 11,518 eggs over the preceding year at that date. This represents an individual increase of 23 eggs per bird. Each year has shown an increase, and the rate of increase is higher this—the third year—than it was the second year. The egg-laying contests have amply justified themselves. The week's record follows:

	Week	Total

GEO. A. COSGROVE.

THE MISSOURI EGG-LAYING CONTEST.

THE June report of the Mountain Grove contest states some very interesting facts. The station has 50 or more pullets hatched this year that have begun to lay when four months old, or a few days over. In every case these early laying pullets were bred from heavy laying hens. The 13 which began laying first were three Buff Leghorns, two Barred Rocks, four White Leghorns, one Ancona, one Campine, one Rhinelander, and one White Orpington. The Barred Rocks and White Orpington weighed from 3½ to four pounds each; the others weighed from 2½ to 3¼ pounds each. The first two pullets to lay were a Buff Leghorn weighing 2¾ pounds, and a Barred Rock weighing 3¾ pounds. These laid when four months and five days old. They were fed cracked corn and wheat, equal parts, for grain feed, and a dry mash in hoppers consisting of equal parts of cornmeal, wheat bran and shorts, with one pound of fine salt to each hundred of mash. Sour milk or buttermilk was fed when it could be had; when not to be had 10 pounds of beef scrap was added to each hundred of mash. At about four o'clock in the afternoon a moistened mash was fed, just the dry mash wet with sour milk or water, giving them all they would eat in 20 minutes. Grit, oyster shell, and charcoal was fed either dry or sometimes mixed in the mash.

Mr. Quisenberry states that in culling 6,000 head of these young birds at the time some of them had begun to lay, only *two birds* seemed to be out of condition. Mr. Quisenberry makes a strong point of hatching in early Spring when the grass starts to grow, and all nature is putting on new life. A point he does not mention, but which is worthy of much consideration, is the further fact that the worms have come up, and the chick has plenty of the tenderest meat, which later in the season it does not have.

Director Quisenberry states that the fourth generation of fowls since the station was established, are now on the farm. The first year a pen of Buff Leghorn pullets was trapnested, which averaged between 90 and 100 eggs. The best layers were mated with a cockerel from the best hen, and that course followed since. Last year they had developed a pen of ten pullets that averaged nearly 200 eggs each, one laying 217 eggs; and this year a pullet from this lot is laying at four months and five days of age; the first to lay out of 6,000 chicks.

POULTRY SURGERY.—A Black Langshan hen remained on the nest most of the time; it was thought she was broody; but in taking her from the nest the caretaker could feel eggs in the abdomen and hear the shells grate on each other. It was a contest hen, but as she would die if left alone, it was decided to cut her open. It was done, and six full-sized normal eggs with hard shells, were taken out from the abdomen. The body cavity was filled with these eggs. The incision was sewn up, and at the present time the hen appears to be perfectly well and happy. This is the third time a similar case has happened among the Black Langshans. In the other two cases the bird died before it was known what the trouble was.

Of the 1,040 hens in this contest, 425 have been broody during some part of the month. This has cut down the egg output to 16,430, for the month of June. The total output is 106,579. Barron's White Leghorns from England are still gaining each month. They have ranked first, five of the seven months. The ten highest pens are:

	EGGS.
White Leghorns, England	1,569
S. C. Reds, Missouri	1,333
White Leghorns, Pennsylvania	1,309
White Leghorns, Missouri	1,277
White Wyandottes, Pennsylvania	1,271
White Leghorns, Missouri	1,248
White Leghorns, Pennsylvania	1,244
Barred Rocks, Illinois	1,201
White P. Rocks, Arkansas	1,196
White Orpingtons, Pennsylvania	1,192

One of the English Leghorns has the highest individual record, viz. 171; the next highest being a R. C. Red with 158 eggs.

GEO. A. COSGROVE.

Infectious Diarrhoea.

WHAT is the matter with my young chickens? They seem to do well until they are between three and four weeks old; then they begin to lose flesh and do not eat well. They keep getting weaker until they die. They eat their droppings at that time and leave their feed. MRS. P. J. H.

Broome Co., N. Y.

I am afraid that there is nothing that you can do to save the chicks already affected, as they are dying from an infectious diarrhœal disease that is preventable but not curable, so far as I know. The remedy is thorough cleansing and disinfection of the brooders, coops or other quarters used by the chicks and hatching, if possible, from other stock whose chickens have not shown similar symptoms. With a broom and hot, soapy, water scrub all brooders or chick coops until they are thoroughly cleaned, then expose the interiors to the sun to dry. Whitewashing with lime wash to which four ounces of crude carbolic acid to the gallon has been added is a further means of protection. Place the brooders upon new ground not previously used by affected chicks, and if you can obtain it, feed your chicks from the start upon all the soured skim-milk that they will drink; use this soured milk also in mixing any moist mash that you feed them. An excellent mash for your chicks may be made of equal parts of cornmeal, wheat bran, wheat middlings, and sifted beef scrap. Moisten this to a crumbly consistency with sour milk and feed your chicks grains in addition. Starting with healthy chicks and taking these precautions to avoid their becoming infected you should overcome your present trouble, but I know of nothing that will save such of the chicks that you now have as are already seriously diseased. They will probably continue to die until only the strongest are left. M. B. D.

Prevention of Lice and Mites.

WHILE I am using a good disinfectant and lice powder, I want to get something better if possible, or to last longer. By using the above in my poultry buildings once a month I am totally free from the pests, but I understand that if one paints his roosting quarters with mutton-tallow he will save one-half the labor that he uses when the spray disinfectants are used. I have heard that if a sheep were kept in a part of a poultry house, one would never see lice or mites. Is this so? F. T. H.

Adelphia, N. J.

Any kind of oil or grease is destructive to the parasites that prey upon poultry but the hard greases like mutton tallow have this advantage that when painted upon perches, etc., after being liquefied by heat they fill the pores of the wood and remain as a coating upon the surface for a considerable time. Beef tallow would be equally good and either may usually be obtained from local butchers. The natural oil of a sheep's fleece would probably protect it from poultry lice but I know of no reason for thinking that a sheep would be destructive to the lice in a building or a protection to hens, unless they roosted upon its back. M. B. D.

Feeding Dry Mash.

CAN you give experience with the dry mash system of feeding poultry, both young and old stock? I pursue that method but am suspicious of its desirability except as a means of forcing egg production. D. H. C.

Vineland, N. J.

I think that there is little question in the minds of most practical poultrymen that the dry method of feeding poultry is superior to any other. This does not mean that all solid food given chicks or hens should invariably be dry; a moist mash fed once or twice daily to growing chicks will hasten their growth and maturity and may well be used for this purpose. Laying hens will also eat more moist mash than dry and this fact may be taken advantage of to temporarily force egg laying. The labor saving in hopper feeding of dry mash is sufficient to counterbalance a considerable increase in production produced by using wet mashes and there is little doubt that the health of fowls is conserved, their longevity increased, and their total production fully maintained where they are given free access to ground grains and are fed sparingly, if at all, upon wet food. M. B. D.

PUBLISHER'S DESK

I AM sending you my renewal. I wish I were able to renew for the rest of my life at one time. I am saving every copy to refer to, and I find them one of the greatest helps. The advertisements are worth money to me, because I always got honest dealing and quick action. I would not think of answering an advertisement in any other paper. I could keep on saying good things of you, but will not take your time. I hope that of all the good things that happen you will have an extra lot dropped at your door. J. T. L.
Indiana.

It is rather a severe indictment of the agricultural press that any farmer feels himself limited to one paper for the safe patronage of its advertisers. This correspondent gives us no intimation of the extent of his acquaintance with the press generally; and for this reason it may be said that he would feel an equal confidence in at least some other publications if he knew them equally well. We hope the time is not far distant when this may be truthfully said; but we have some acquaintance with the press, and some knowledge of the character of advertising, good, bad and medium, that is found in the publications of general circulation; and we are frank to say strictly speaking this correspondent is on safe ground. There is scarcely an issue of a farm paper or other publication of general circulation coming to our desk that does not carry one or more advertisements that we have rejected and refused. Many of them we have publicly criticised. Farmers who patronize these advertisements in other papers are constantly appealing to us for redress because the publishers who carry the objectionable advertisements neglect or refuse to protect the complainants. The strange part of it is that while we reject the advertising we are often able to get adjustments for the patron, after he has been turned down both by the advertiser and the publisher who carried the advertising. So while the indictment is a little severe, the publishers are themselves responsible for it. It is not enough to reject advertisements that are, as one farmer puts it, as "crooked as a rail fence." If they wish to enjoy the full confidence of the reader, they must reject everything that suggests an encroachment on a square deal.

Enclosed is correspondence to add to your collection of experiences. G. E. M.
New York.

The correspondence referred to extends from June 6, 1912, to March 27, 1913, between this subscriber and the Wisconsin Fur, Wool & Tanning Co. of Eau Claire, Wis., over a shipment of 38 fleeces of wool weighing 197 pounds, which according to the quotations at the time the shipper valued at 27 cents per pound, or $53.19. On July 24 and Sept. 13 the Wisconsin Fur, Wool & Tanning Co. reported to the shipper that the wool had not been received, whereupon the shipper made claim against the Delaware & Hudson Railroad Co. for the value of the shipment. The correspondence with the railroad company continued until Nov. 15, when the railroad company reported that the shipment in question had been delivered on July 28. The consignee contends that the shipment was delivered without the name of the shipper, and yet questions whether the wool came from our subscriber or not, but makes returns for 177 pounds at 15 cents per pound, which after deducting the freight charges, nets the shipper $23.88. This amount the shipper contends is about one-half what he might have received for the wool at home, had he not relied upon the representations of the Wisconsin concern, which induced him to send the shipment to them. We fear the subscriber will have to charge his loss up to experience. He sends us the record of the transaction for the benefit of other subscribers in the hope that they may be saved from a similar loss.

What do you think of the inclosed bunch of get-rich-quick schemes, especially the two gold mine ones? L. D. M.
New Hampshire.

The collection of literature referred to above includes that of Wm. G. Krane Inv. Co., Inc. of Denver, Colo., promoting the stock of the Crown Prince Consolidated Mines Co.; Cyrus W. Barnholt of Denver, Colo., who seems to be promoting an unnamed mining scheme; literature of a rheumatism cure, and a mail order proposition. The subscriber pretty accurately describes the collection himself when he calls them "get-rich-quick" schemes. Another subscriber accurately expressed our estimate of these mining propositions in this department sometime ago when saying that the only difference between them and pouring money into a rat hole is that it might be possible to dig up the rat hole and in that way get the money back, while there is no possible chance of ever seeing it again when the money is turned over to one of these promoters and schemers.

Here are four interesting, but most unsatisfactory records:

M. Rappaport, 2347 Nicholas St., Philadelphia, Pa. Check was sent in settlement but when it was returned for minor correction nothing further was heard from it: Mr. Rappaport conducts a butter and egg route and is out all day but he pays no attention to requests for settlement.

Fergus Ferguson, 14 Kosciusko Street, Brooklyn, N. Y., neglected to remit for egg shipments. He has now removed and left no address.

F. A. Slater & Co., 22 Clinton St., Newark, N. J., acknowledge receipt of a case of eggs but failed to pay for same. The report is now that they have disappeared and left no trace.

Wm. M. Manee, 5912 Utrecht Ave., Brooklyn, N. Y., solicited and received egg shipments, and paid for same up to a certain time. Two cases of eggs sent in May, 1913, and delivery proved by the express company, are still unpaid for and Mr. Manee fails to respond to requests for settlement.

We suggest that these records be kept for future reference. The usual thing is for men of this kind to change their address, and often their names and solicit shipments. Sometimes they solicit shipments under the old name and address from an entirely different section of the country. They never give up the game.

The case of the defunct Kornit Manufacturing Company that has been on the calendars of the criminal and civil courts for several years, ended yesterday when the Referee in Bankruptcy, Edwin G. Adams, filed a memorandum in Newark fixing the sum of $3,500 to be divided among the creditors while $6,000 was allowed to the lawyers in the case.

Through fraudulent representations the promoters of the Kornit concern obtained thousands of dollars from investors. As officers of the concern Charles E. Ellis and Erwin R. Graves were convicted in the Federal Courts and were sentenced to the Federal Prison at Atlanta.

The above from a local paper closes the record of the Kornit fraud. Ellis and Graves published several cheap mail order papers, among which were the Metropolitan and Rural Home, an alleged farm paper. This paper was originally published to advertise Warner's patent medicines in Rochester, N. Y. Later it fell into Ellis' hands. He claimed a half million or more subscribers for it. It did not cost the subscriber much directly to get the paper, but he afterwards paid rather liberally through the patronage of fake advertisements and the Ellis promotion schemes. At one time the business seemed most prosperous. Ellis had an elegant country home in one of the fashionable suburbs of New York, and had one of the largest and best stables in the place. He also made large investments in New York City property. Stock in the Kornit company was sold to the readers of the Ellis papers. To establish the confidence of the public, contributions on agricultural subjects were purchased and published over the names of some of the best known teachers and writers on farm subjects. These writers were simply used to secure an element of respectability for the paper, and to win the confidence of farmers for the Ellis schemes. Money poured in fast. Then came the announcement of a fire, and a request for more money and an assessment from those who first contributed. Following this came an indictment and trial. It was testified on trial that no record was kept of the money that came in. All went into the same till. Ellis and Graves got a little time at the Atlanta Federal prison: and of all the hundreds of thousands of money contributed, the creditors now get back $3,500. Farmers ought to realize that they have a responsibility in such matters not only to avoid the encouragement of such enterprises themselves, but to protect their less informed neighbors against them. Teachers in agricultural colleges and agricultural writers should also avoid turning the influence of their names over to help the promotion of such schemes. They have all had rather frequent reminders of the result of such influences. So long as publishers following the Ellis and Graves methods are able to secure a half million subscribers to their fake publications while publishers of legitimate papers must be content to struggle along with a few thousand readers, we shall have publishers to imitate the Ellis and Graves methods.

Sweeny.

I have a young horse that was sweenied last Winter working in the plow; have tried to cure it but so far have not been able to bring back the muscles to normal condition. I put in a seton and followed it with a blister but the result is not satisfactory. Can you tell me of a good remedy for a case like this?
California. H. A. S.

It requires a long time to restore the wasted muscles in such cases, and severe treatment rarely succeeds. It is much better practice to stimulate flow of blood to the parts by rubbing them thoroughly several times a day, and at the same time pulling the skin away from the bone. Many use corncob, instead of the hand, for the rubbings, as this gives more friction. In addition to the rubbing use a liniment composed of one part each of turpentine and aqua ammonia and six parts of raw linseed oil. Rub this in each night until the skin starts to get sore; then stop using liniment until the skin recovers. It is a mistake to blister severely with the liniment. If possible keep the horse at light daily labor in a heavy breast collar. If you cannot work him make him take lots of exercise every day. It may take a year for the muscles to grow in again. A. S. A.

The Powerful Smalley Cuts Silo-Filling Cost!

The day of the old slat-apron silo filler is gone. No wise farmer is going to use one when he can get a money-saving, **grip-hook, force-feed SMALLEY,** that does the work quicker, easier and at less cost. It handles silage, cow peas or alfalfa in a hurry. Cuts it fine and uniform. Packs silage tighter—gives more tonnage.

No Power Waste

One pulley and chain-drive on blower outfits replace power-wasting idlers.

1914 Carrier

A 5 H. P. Engine will run a No. 12 force-feed and our 1914 enclosed carrier. Special alfalfa grinding screen furnished extra, protected by screen patent No. 721,246. Make your own meal.

Send postal today for latest Smalley catalog.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending July 31, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914.	1913.
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.51 and $1.41 for B and C. Hotels and restaurants using two to three cans per day are paying five to 5¼ cents per quart single quart prices from bakeries and grocery stores, six to seven cents; delivered milk, nine to 10 cents.

BUTTER.

The net price result for the week has been a half-cent advance on the better grades. Buyers for fancy trade found trouble in getting enough of the quality desired, the great majority being stock valued at 25 to 26 cents. Business in city-made butter and packing stock is quite good, mainly on basis of 18 to 20 cents.

Creamery, extra, lb	28	@	29½
Good to Choice	23	@	27
Lower Grades	20	@	22

Young America	16	@	16½
Limburger	15	@	17
Roquefort	28	@	30
Stilton	46	@	48
Parmesan	25	@	28

EGGS.

This week has added another cent to the top qualities. The price range is now very wide, as the medium and low grades are in surplus and prices freely cut to make sales. Some of the egg candlers struck, but their places have been filled by non-union men and girls, the latter being quick to learn this work.

White, choice to fancy, large	29	@	30
Common to good	22	@	26
Mixed colors, best	26	@	28
Common to good	17	@	20
Western fresh, white	21	@	22
Lower grades	15	@	18
Storage, best	24	@	25
Seconds	22	@	23

FRESH FRUITS.

There is considerable surplus of windfall and cull apples. Good-sized hand-picked are selling well. Peach prices have improved slightly, though the increase applies to but a small proportion of receipts—fancy Elberta and Belle of Georgia. Currants and other small fruits damaged by rain. Muskmelons in heavy receipt and lower on all grades.

VEGETABLES.

Potato receipts have increased so largely that prices are 50 to 75 cents per barrel lower. The nearby crop is good, both in size of tuber and quality. Jersey corn selling in wide range of price—$2 per 100 for best. Cucumbers in surplus and very low. Squash selling mainly at 50 to 75 cents per barrel. Tomatoes arriving in bad condition because of wet weather.

GRAIN.

The high prices prevailing in the great markets this week are largely speculative, owing to war movements in Europe. Wheat is the first grain to be affected by a war scare, but the market on all other grains soon feels the pinch. There will be many "flurries" in wheat, as well as other products if the proposed crude, costly and altogether deplorable method of adjusting difficulties holds in this case. It would not be considered sensible for a farmer or business man to settle disputes with his hired man or partner in such blood and thunder fashion. The result might be profitable for menders of broken heads and vendors of arnica and sticking plaster, but bad for most others.

WOOL.

Ohio fine unwashed	28	@	29
Quarter blood combing	27	@	27½
New York Fleeces	23	@	24

July 22. The markets here are very unsatisfactory, as most of our produce has to go through the local merchants. Shipping facilities are poor, as the only railroad through this part of the State is the Great Northern at Kalispell, 20 miles away. Prices, when there is a chance to sell, are something like this: Butter 25; eggs 20; potatoes 50-75 per 100 pounds; wheat $1.50 per 100 pounds; oats $1.25; strawberries $1.75 to $2 per 24 quart crate; cherries 90 to $1 per 10 pound crate, $2 24-quart crate. Milch cows $50 to $75; hogs 8; baled hay $12 to $15. Apples in season $1 to $2 per box. Strawberries, and in places garden crops were cut short by late frost; grain fair crop. Quite a fruit industry is being developed, especially around Flathead Lake, such as apples, cherries and plums.
Bigfork, Mont. M. O. E.

Labor Agents in Nebraska.

I WAS very much interested in the article by John Anderson & Son in their effort to get help from New York and their putting up $5 to the labor agent. I am a labor agent, have been in the business for 28 years, and we make a specialty of farm help. We have over 100 farmers we furnish help for and some of them have been getting help from this office for 22 years. I have been sending out farm hands when the best wages were $20 per month on a farm where now it is $30 to $35 and even $40 per month. We have farmers who get one man and possibly two in a year. We also have farmers who get from 100 to 150 hands during the year, but of course these farmers have several thousand acres in grain. I am getting help for a farmer here now in Iowa, who has 3,100 acres of corn, 2,000 acres of grain and 1,600 of hay to care for. Instead of charging them $5, as the New York man does, we charge them nothing and we guarantee them good help, and then they come back again for help the next time; in fact we send out nothing but first-class farm help, and they have to pass an examination before we book them for any farm job. We send out no Italians, Greeks or negroes unless we have an order, but we have never had an order for one of these nationalities except one negro in 27 years. Our farm help in this part of the world consists of Americans, Swedes, Danes, Bohemians, Germans, Polish, Austrians a few. These farm hands all pay an office fee at the office; they also pay their own railroad fare to the work. But we guarantee them work and at the wages agreed upon at the office. H. E. W.
Nebraska.

Cellulitis.

MY horse suddenly became lame in left front foot; limped just a little all day; could not find anything at all wrong. The third morning it broke at top of hoof, and suppurated. Later it broke on back of leg just below second joint. Both places have been running badly since. It has a very bad smell; the sore is eating all the time and have failed to get anything to stop it. It now bleeds at times until horse is very weak. What can be done? J. W. E.
West Virginia.

Infection has spread in the connective tissue from the original wound, and it is unlikely that home treatment will avail. A qualified veterinarian should be employed and should give hypodermic injections of antistreptococcic serum. Bathe the sores twice daily with a 1-1000 solution of bichloride of mercury, then dust freely with a mixture of one part of iodoform and six parts of boric acid, covered with absorbent cotton, and clean bandages. A. S. A.

Indigestion.

LAST Summer my horse commenced to run down. I doctored him for pin worms with good results. The horse seems to be lifeless and very poor, but has a good appetite. A. T. C.
Massachusetts.

Have the teeth attended to by a qualified veterinarian. If the coat is long and rough have it clipped, work or abundantly exercise the horse every day. In feed night and morning mix a tablespoonful of a mixture of equal parts of dried sulphate of iron, powdered nux vomica, gentian root, fenugreek and saltpeter. Continue this medicine for 10 days; then skip 10 days and repeat the treatment if found necessary. A. S. A.

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

WANTED—A housekeeper for small family. A. H. PENNY, Mattituck, N. Y.

EXPERIENCED MAN wishes position as farm foreman or herdsman; married; best references. K. E., care Rural New-Yorker.

FIG PRESERVES—Home made; a new delicacy for most people; made from choice fruit right from the tree; few people have ever tasted a fig as it ought to be; write for prices and sample to MRS. M. A. PARKER, Rickerly, near Dauphin way, Mobile, Ala.

105-ACRE FARM—Good buildings; 3 miles from county seat; will exchange for small farm. JOSEPH HAMPTON, Flemington, N. J.

WANTED—Southern Connecticut farm for fruit; 20 acres up; elevated above adjacent land; Western view; Colonial house preferred. HARLEY KENDALL, Norwalk, Conn.

FRUIT, TRUCK, POULTRY FARM—Will sell all or any portion of 36 acres; good buildings, excellent location; immediate possession; no agents. HOMER TWEED, Quakertown, Pa.

TO LET ON SHARES—A well-equipped farm of 165 acres, half of it in cultivation in Bergen County, N. J., adapted to dairying, pig raising or truck farming. M. N., Rural New-Yorker.

WILL SELL—Two sections timber land, oak, latitude 37; or exchange for farm near latitude 40, in Ohio; age of trees about 70 years. L. W., care Rural New-Yorker, 333 West 30th St., N. Y. City.

TWO FARMS FOR SALE—One of 67 acres, level; good 8-room house and other buildings; another of 63 acres, fruit and poultry farm, one-third set with peach, cherry and quince trees; part in bearing; write for particulars. G. W. BLAINE, Califon, Hunterdon Co., N. J.

100 ACRES—Irrigated ranch; feneed; 50 acres broken; at Los Alamos, New Mexico; 10 miles from Las Vegas; 3 miles from Onara P. O., main line Santa Fe R. R.; very fertile soil; home of Alfalfa; 6,500 ft. elevation. Address Owner, CHAS. ED. MOYSES, Oyster Bay, N. Y.

FOR SALE—Beautiful property, ¾ of a mile from station, post office and school in Village of Washingtonville, on the State road between Newburgh and Goshen; 230 feet front and 210 feet deep; house of 11 rooms with all modern improvements. Write or call on REV. JOHN TETREAU, Washingtonville, N. Y.

A METHODICAL, practical, scientific and successful general farm and dairy manager covering years of extensive and varied experience in exacting operations will be open for engagement Sept. 1. Eminent credentials will be furnished and nothing short of a first-class, responsible and remunerative position will be considered. If desirous, might consider cash proposition of lease of entire property. Address T. J. A., care Rural New-Yorker.

DO YOU NEED FARM HELP

We have many able-bodied young men both with and without farming experience, who wish to work on farms. If you need a good, steady, sober man, write for an order blank. Ours is a philauthropic organization and we make no charge to employer or employee. Our object is the encouragement of farming among Jews. **THE JEWISH AGRICULTURAL SOCIETY, 176 Second Avenue, New York City.**

The FARMERS' BUREAU an agency exclusively for agricultural help. Only first class farm help and positions solicited. References investigated. Scientific advice on farm problems. Dept. R, 150 Nassau St., N. Y. Phone, 5565 Beekman

Farm for Sale—Ten acres, improved, near Vineland, on trolley car line. Particulars from **M. M. PRESCOTT, Millville, N. J.**

HUMOROUS

FALLON (who has bought a small farm): "Tell me the truth, Mr. Carney, is the soil rich or poor?" Expert Gardener: "Well, sor, I should say it wor wanst rich, but it's now in raydooced circumstances."—Melbourne Leader.

THE SUPERIOR ONE (who has swanked into the village shop): "Do you sell puppy biscuits in this one-eyed little shop:" The Shopman (getting his own back): "Certainly, sir. Shall I put them in a bag for you to take home, or will you eat them here?"—The By-stander.

THE young wife came hurriedly into her husband's study one morning. "Herbert, dear." she said. "this recipe for apple pie tells you to sit on a hot stove and stir constantly." "Well, Alice," replied the mere male, "if you do sit on a hot stove, I think you will find that you will stir constantly."—N. Y. Evening Post.

WHEN the young physician's motor car reached the scene of the accident there was nothing to do; all the victims had been so slightly hurt that they were able to walk home. The young doctor was keenly disappointed, but his chauffeur spoke up cheeringly: "Never mind, doctor. I'll run down some business on the way home."—Credit Lost.

THE Sunday school teacher was making a review of the lessons. "Who was the wisest man, James?" "Solomon." "That's right. Now Frank. who was the strongest man?" "Jonah." "Wrong; but what reason have you for believing Jonah was the strongest man?" "'Cause the whale couldn't hold him after he got him down."—National Monthly.

"WHAT do you want with all those hammocks and phonograph records and fancy groceries?" asked the storekeeper. "Going to have Summer boarders?" "No," replied Farmer Corntossel. "I wouldn't waste all that on Summer boarders. I'm tryin' to make the place attractive enough to persuade a few farm hands to linger around an' help me out with the wheat crop."—Washington Star.

MRS. R. was an extremely careful mother, and had repeatedly cautioned her six-year-old daughter against handling any object that might contain germs. One day the little girl came in and said: "Mother, I am never going to play with my kitty any more, because she has germs on her." "Oh, no," replied her mother, "there are no germs on your kitten." "Yes, there are," insisted the child. "I saw one hop."—Harper's Monthly.

"YOUNG man." said the proud father. "in giving you my daughter I have entrusted you with the dearest treasure of my life!" The young man was duly impressed. Then, during the few minutes of impressive silence that followed. he heard the patter of rain against the window-pane. "Oh," he exclaimed. "It's raining, and I haven't my umbrella! May I borrow yours to get to the station?" "Young man," said the parent, "I wouldn't trust anybody on earth with my umbrella."—Australasian.

MRS. Flint came for a visit to her sister's home, and her little niece, Charlotte, was delighted to see her. "What became of the black kitten that you had when I was here before, dear?" asked Mrs. Flint. "Why, don't you know?" asked Charlotte, much surprised. "I haven't heard a word." replied the aunt. "Was he poisoned?" "No. ma'am," said Charlotte. "Drowned?" "Oh, no." "Stolen?" "No." "Hurt in any way?" "No, ma'am." "Well," said Mrs. Flint. "I can't guess, dear. What became of him?" "He growed into a cat," said Charlotte. —Credit Lost.

SAVE HALF Your Paint Bills

By using INGERSOLL PAINT—proved best by 66 years' use. It will please you. Only paint endorsed by the "Grange." Made in all colors—for all purposes.

Ground Limestone 50c Per Ton

The day of cheaper lime is here. No need to let your soil stay sick and sour because of the lack of lime if you have lime rock available. No need to let acid land keep you from growing clover or alfalfa. With a Jeffrey Lime Pulver you can grind lime-rock right on your farm at a cost of 50c per ton! This does not include quarrying cost, which varies, but in some sections is almost nothing. Ground limestone is better than burnt lime. It doesn't burn up the humus or waste the Nitrogen in the soil.

Dig out those lime rocks that prevent your cultivating your fields. Feed the rocks to the Lime-Pulver, as large as you choose—any size up to 4 inches thick and 11 inches long. The rocks disappear in the hopper. Out of the funnel pours a stream of ground limestone—ground either coarse or fine. It's like turning rocks into dollars—"making bread from stones."

Grinds 2 to 3 Tons Per Hour
Grinds Rock for Road Work Too!

Home Grinding of Limestone PAYS!

A 2 in 1 Crusher and Pulverizer Grinds the Big Rocks—Big Capacity

The Jeffrey Lime-Pulver is the machine that will take the big rocks that come from the quarry and grind them to a powder that will go through the spreader. It is both a crusher and a pulverizer—with twice the capacity of other crushers. Grinds from 2 to 3 tons per hour. Grinds rock for road work and concrete work—grinds corn on the cob, tobacco stems, bone or any similar material—a universal grinder, portable—as easily moved from place to place as a wagon. Built to last a lifetime—with pulverizing hammers of Manganese steel—hall bearing pulverizer. Sold on a guarantee of satisfaction or your money back. Write us today for our free booklet giving price and full information about the Lime-Pulver. Write NOW.

Bale Hay! Big Pay!

This **Free Book** tells of profits baling hay. Sandwich owners lead all others: Make $200 to $300 clear profit every month baling hay for growers in their district. "32 tons in 8 hours with a 3-man crew" writes C. W. Brown, Merrill, Michigan. Plenty more bale 20 to 30 tons daily, rain or shine. **Big Tonnage.**

SANDWICH Hay Presses

This mighty, solid steel **MOTOR BALER** supplies its own power from high grade, hopper cooled, Gas Engine, 4, 6, 8 or 10 H. P. mounted on same truck. Geared Magneto. No break downs. Another exclusive feature—full power delivered to Press by heavy steel roller chain. Turns out solid, salable bales. No dangerous belts to slip or stretch in wet weather. No other baler has this friction clutch on press, can start or stop instantly. Simple self-feeder that stands hard crowding. We make Horse and Belt power presses too.

Grasp This Golden Moment

and mail a postal for our famous "Tons Tell" catalog that shows you in actual figures the money made with the Sandwich Press and how you can pay for your press from your first year's earnings. Sent **free** postpaid. Address today.

A FINE EGG-LAYING RACE.

The American Leghorns Pictured.

IF in the coming yacht race between England and America the two boats come into the last mile before a good stiff breeze, and hardly a foot of distance between them, the two nations would about stand on their heads with excitement until it was over. The egg-laying contest at Storrs promises to give a finish nearly as exciting. For months the English Wyandottes have been far in the lead. The English Leghorns are now coming up at a lively pace, but they were too far behind before they began to catch up. Two pens of American Leghorns have made rapid gains, gradually crawling up to the English Wyandottes. At the end of July or the thirty-ninth week of the contest the record was as follows:

	EGGS
White Wyandottes (Tom Barron)	1,636
White Leghorns (Conn. Agri. College)	1,637
White Leghorns (Francis F. Lincoln)	1,615

The Leghorns from the college were entered to give an experiment in feeding, and thus are not considered in the contest. The real contenders with the Wyandottes are the Leghorns owned by Francis F. Lincoln. We have already pictured the Wyandottes, and so this week we show a picture of Lincoln's Leghorns, taken in their pen at the egg-laying contest. A brief statement of what these birds have done is given below—figured up to July 1 or eight months in all:

FEED CONSUMED.

Mash.	Grain.	Oyster shell.	Charcoal.	Grit.
Pounds. 208	*Pounds.* 427.4	*Pounds.* 20.88	*Pounds.* 2.66	*Pounds.* 10.25

COST OF FEED.

Mash.	Grain.	Oyster shell.	Charcoal.	Grit.
$3.59	$7.65	$0.15	$0.05	$0.08

Total number of eggs 1394. Total weight of eggs 164.22 lbs.

WEIGHTS OF BIRDS.

BIRD...	1	2	3	4	5	6	7	8	9	10
Nov. 1.....	3.0	3.6	3.8	3.2	3.2	3.6	4.5	3.2	3.7	3.2
Jan. 1.....	3.4	3.6	3.6	3.7	3.4	3.6	4.3	3.4	3.8	3.3
Mar. 1.....	3.4	3.6	3.5	3.6	3.2	3.5	4.5	3.6	4.3	3.5
May 1.....	3.5	3.8	3.75	3.6	3.4	3.2	4.5	3.5	4.1	3.6
July 1.....	3.25	4.0	3.75	3.5	3.5	2.8	4.25	3.7	4.25	3.3

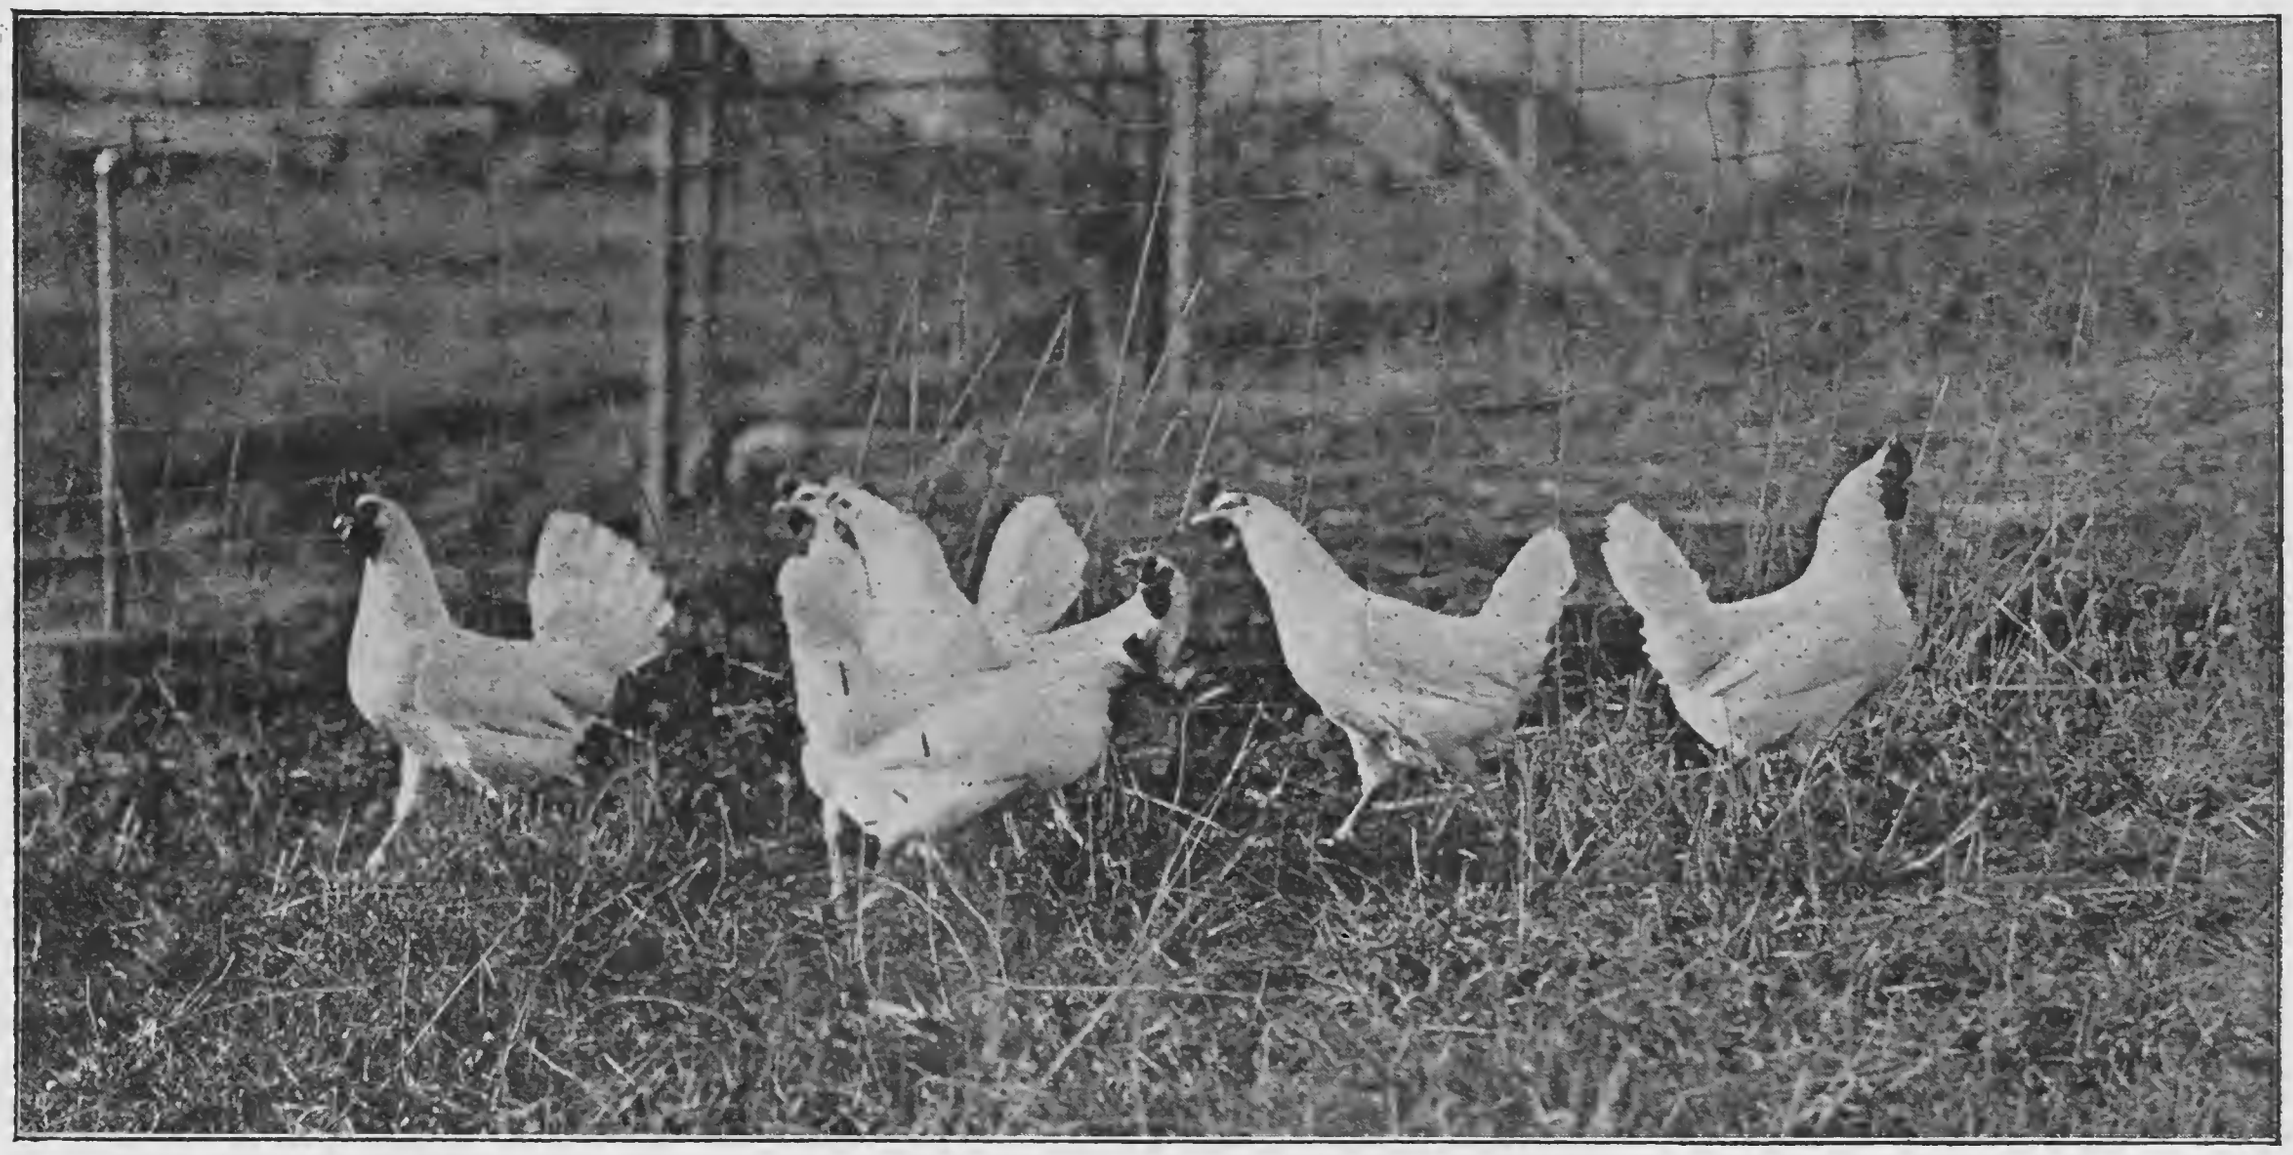
Thus it will be seen that the food for these hens cost $11.52. Mr. Lincoln has kept a careful record of the values of the 1,394 eggs, many of which were laid when the price was very high. This egg value is $47.74. Thus each hen averaged 139.4 eggs in eight months at an average food cost of $1.15 and an average earning value of $4.77. The average consumption of food per hen for eight months is 20.8 pounds of mash and 42.7 pounds of grain. This means 1.37 ounces of mash and 2.8 ounces of grain per day. Mr Lincoln gives us the following statement about his birds:

My birds are American Leghorns, bred for egg-laying for many years, though I haven't handled them long. My first males came from Merritt M. Clark, Connecticut, and I think are White and Rice blood; the females came from a farm in New York where the strain had been trap-nested for several years. Crossing this unrelated blood I think I have a strain of exceptional vigor and laying ability.

When I had entered a pen for the present egg-laying contest, my problem was to pick the best 10 from about 200 pullets, all of which would be in laying condition at least by November. I thought the pullet that used its food efficiently in growing would continue that efficiency when laying, so when, in early September we did our first selecting, we picked the 16 pullets that seemed nearer maturity than the rest, and it was a job. I like a layer to be pretty small, long-backed, deep in the back, with legs well apart and a short, sometimes almost stubby beak, and while the main point I looked for was the quickness with which a pullet approached maturity, the comb is a good signpost for this. I kept the type in mind and would do it again. The 16 were gradually culled and one was added later until we had the number required.

These pullets would ordinarily have started laying late in September, but I knew the probability of their molti-g if they had laid much at home before being shipped, so for a month and a half we moved them often enough so that they would never feel at home enough to lay. All beef scrap was taken from their mash, but I couldn't stop them entirely and the 10 birds did lay perhaps 30 eggs before they left home. When they reached the contest they spent a week getting settled, then started in hard, were the leading pen for November, second for December, have kept persistently at it ever since. FRANCIS F. LINCOLN.

The contest between these Leghorns and the English Wyandottes will be a close one. Mr. Barron thinks his birds have gained their second wind and will keep ahead while Mr. Lincoln says his birds "have lots of lay in them yet." It is a pretty race—may the best pen win!



PART OF THE LINCOLN LEGHORNS—SECOND PEN IN THE EGG-LAYING CONTEST. FIG. 427.

NOTES ON GLASSHOUSE GARDENING.

Brooder House as Greenhouse.

MY brooder house has windows in the entire length of its southern side; hotbed sash in the roof make it suitable for use as a greenhouse from September 1 to February 1, when it is not occupied by chicks. What is the best single crop or succession of single crops I can mature in that time? I wish a flower or vegetable crop that I could readily sell, and that would be suitable for a man having little greenhouse experience, but who thoroughly understands the handling of hotwater heaters and the importance of a constant temperature? J. L. L.
New York.

Here is a brooder house with windows in entire south side and hotbed sash in roof, that the owner wishes to use as a greenhouse from September 1 to February 1, either for flowers or vegetables. If the sash in roof are continuous on each side of ridge similar to a greenhouse roof, either tomatoes, rad-

ishes or lettuce could be grown. If sash are placed only at intervals at one side success would be problematical, and could only be determined by experiment, as very few plants make a growth that would be profitable commercially unless light in abundance strikes them from every angle, especially during the dark days of Winter. Tomatoes would be my preference for such a house. The seed should be sown July 1, and plants kept growing rapidly and finally placed in large pots, or boxes about 10 inches square and six to eight inches deep in good rich soil, trained to a shape, and all suckers kept off main stem. Bonny Best would be best variety to grow. A good crop of fruit would set outdoors, and some time during September the boxes could be placed in house where the fruit would mature during November and December. If the plants were to become root bound in pots or boxes they could be shifted to larger pots, or if in boxes the bottoms could be removed and boxes set on a few inches of fresh soil. If the roots are given too much liberty the fruit will ripen late; 56 to 60 degrees at night and 75 to 80 degrees day time would be good temperature. Water freely, or black rot at blossom end will develop.

The late varieties of Chysanthemums could also be experimented with by growing in pots out doors under canvas till frost, then placing indoors, though the success would be doubtful. The season would be too short to develop any other flower that I know of at present.

Chemical Fertilizer for Dahlias.

WILL you tell me what would be the proper amount of phosphoric acid and potash to use on Dahlias, per plant, and how to apply it? Is it possible to apply a sufficient quantity to be harmful? Give quantities in using acid phosphate or bone meal; sulphate of potash or wood ashes.
Massachusetts. W. H. J.

In sandy soil, which is the only type of soil in which the Dahlias can be profitably grown season after season, chemicals give very good results, and the formula generally used is a high-grade potato manure of about two to three nitrogen, eight to nine phosphoric acid and 10 potash. This formula can be used with advantage at rate of 1,200 to 1,500 pounds per acre, preferably in two applications of several weeks apart, when cultivating in Spring. If clay soil is used, it is possible that only phosphoric acid and potash would be sufficient, and not a great quantity of these, as with us the Dahlias make all plant and bulbs or roots and very few flowers, and these few are usually ruined in the bud by tarnished plant-bug. W. H. J. can figure amount per plant by number of plants he would set per acre, as he grows them.

Profit in Greenhouse Tomatoes.

I WOULD like to know whether tomatoes raised in a hothouse for the early Spring trade would be a paying proposition in this locality. Southern tomatoes that are picked almost green are shipped in here and retail at 12½ to 15 cents per pound. This seems to me as though it would be a good thing to take up if I had some facts about the extent of glass required to raise a certain amount of tomatoes, etc.
Kokomo, Ind. G. J. C.

There is no question about there being profit in a Spring crop of tomatoes in a greenhouse if properly managed, and other crops of a profitable nature can be grown while the tomato plant is maturing, like lettuce or radishes. The seed should be sown November 1 to 10, and plants kept growing in pots without crowding and planted out in beds or benches February 15 to March 1. By good culture you may possibly obtain four to five pounds per plant, and the plants can be set 16x18 inches or even 16x16 inches apart, so if you have any definite amount in view that you would like to produce, you can figure how much glass would be required to produce that many pounds. In our market greenhouse tomatoes always sell for three to six cents per pound more than the tough southern tomatoes that are picked green. If G. J. C. has a file of back issues of THE R. N.-Y. and will look up articles on a greenhouse for a small place, printed early last Spring, he will find detailed information regarding the handling of tomatoes under glass and several catch crops to utilize space while tomato plants are maturing.

ELMER J. WEAVER.

FITTING PASTURES FOR POTATOES.

WE have a number of acres of run-out pasture land, has not been turned for over 40 years, sod very mossy, soil rather dry gravelly loam, such as is usual in Northern Massachusetts; in places inclined to pack, southern and eastern exposure. In places this land will not grow buckwheat eight inches high. When heavily dressed with ground bone (we have but little stable manure) rye, buckwheat, beans, etc., show fine growth. Lime one ton to acre does not seem to improve crop growth. We wish to fit this land for potatoes in 1915 at least expense for fertilizers. E. A. C.
Massachusetts.

The fact that this land responds to an application of fine ground bone shows that phosphoric acid is the most needed element, and that the nitrogen in the bone also helps. In practically every case where we have tried to refit an old pasture land lime has proved useful, and we think in nine cases out of ten lime will benefit such soil. Even if the soil is not sour the lime will generally help give it a better mechanical condition. We have done considerable work with soils of this character and have followed about this plan:

If it is possible, plow in the late Fall and leave the furrows exposed through the Winter to the frost and weather. This helps to break up and subdue the old sod, and kills out many of the insects. In the Spring work up with a Cutaway harrow and use a spring-tooth also if possible. Fit the land by applying one pound of lime to the acre and plant some variety of flint corn which will do well in that locality. The flints do well on this rough land, and in our experience have responded better to an application of lime than the dents have done. They also mature early, and we are able to start a cover crop to good advantage. We give this corn good culture through the season, and at the last cultivation in August put in a cover crop. With us this means one bushel of rye, either 15 pounds of Crimson clover or 20 pounds of Hairy vetch and two pounds of Cowhorn turnip seed to the acre. This is scattered on the ground and worked in by the cultivator. In the Spring what remains of this cover crop is plowed under, and if the soil is thoroughly fitted it is then in fair condition for potatoes. Under ordinary conditions and with ordinary soil, we would not use lime so heavily one year in advance of the potato crop, but such pasture lands are usually very sour and the cover crop also plowed under seems to overcome to a large extent the effect of the lime. In your case it is now too late to plant flint corn, and we should simply try to put as much organic matter as possible into that soil to fit it for next year's potato crop. We should plow this land as soon as possible and use from 600 to 800 pounds of slaked lime per acre, then apply 500 pounds of a mixture containing three parts of fine ground bone, and one part muriate of potash. Then broadcast a combination of two bushels of buckwheat and three pecks of field beans or cow peas. Let this grow until late in August. Then plow it under and sow as soon as possible the cover crop which we have mentioned above, or any other combination which experience has shown better suited to the locality.

FERTILIZER FOR THE CORN CROP.

HAVE the experiment stations determined whether a complete fertilizer used on a green crop in the Fall to increase growth will pay? Will the increased growth decay in the Spring and Summer, and form nitrates to such an extent as to pay for the nitrates used in the Fall? Notwithstanding the good teachings of THE R. N.-Y. which I think are second to none among farm papers, I think Timothy sown after or among crops is far ahead of anything yet. I would not sow rye and wheat if I could buy Timothy if anyone gave me the other free, to be used to plow under. The Timothy makes a stronger sod, can be sown among any standing crop, and without any covering makes a fair stand; also it can be left to stand longer in the Spring before plowing under. W. S.
Matawan, N. J.

By a "complete" fertilizer we assume that you mean one containing nitrogen, potash and phosphoric acid. We do not think the stations have settled the matter. The plan of using the potash and phosphoric acid on the cover crops is a good one, particularly when this crop is a legume like peas, beans or clover. With such a crop the potash and phosphate give a larger growth and thus the crop obtains more nitrogen from the air. We know one very successful potato grower who had plenty of land and grew a potato crop once in two years. He seeded cow peas in May with a fair dressing of potash and acid phosphate. These peas made a good growth and were plowed under in early September when rye and Crimson clover followed. In the Spring this crop was plowed under, the soil fitted for potatoes—at which time nitrate of soda or a small amount of a special potato fertilizer was used. This gave a soil full of organic matter, and with the chemicals used the year before on the cow peas in an available form. After harvesting the potatoes rye was seeded—to be plowed under the following Spring for another cow pea crop. This system produced large crops of potatoes at a low cost of plant food.

Generally speaking it would not pay to use nitrogen on a Fall-seeded cover crop. One object of such a crop is to utilize the nitrates which are formed in the soil during late Summer and Fall. It would not be good economy to use nitrogen under such conditions, but the potash and phosphoric acid may well be used then. As for Timothy as a cover crop—from our experience we prefer rye, rape, turnips or vetch. One objection to Timothy with us is that it is about the worst weed in hoed crops that we know of. Seeding it ahead of potatoes or garden crops would increase the work of hoeing or weeding.

SHALL HE BUY A FARM TRACTOR?

I AM a young man of limited strength but unlimited determination to succeed; I have very little knack of handling large teams but have a natural mechanical turn. My farm (120 acres) is stony, but has no actual bed rock near the surface. The fields are gently rolling with no steep places. Then the labor problem is at its worst. There are 1,000 apple trees on the place. Would a good reliable farm and orchard tractor pay me as a business investment, considering that there is a large field for outside work, hauling, etc.? S. P. T.

This question ranks with what we often receive from crippled men or farmers with only one leg or arm—"*will it pay me to buy a milking machine?*" Anyone can see with a little thought what a serious thing it is for an outsider or stranger to give direct advice regarding an investment which might mean serious loss to the farm in case it did not turn out well. No one should tell such a man yes or no definitely unless he knows the man personally and has had a chance to study his character and ability. No one claims that farm tractors have yet been developed so that they rank with automobiles in efficiency. All of them must still be regarded as more or less of an experiment. Our friend might find one well adapted to his stony and rolling land, while others would fail when taken away from the level, smooth fields of the west. It would not pay, as a general proposition, to buy a tractor for the work on a 120-acre farm alone but if there is outside work to be done the investment may pay. There is no question but that more and more of the future farm work will be done by tractors when the machines are made more practical and better adapted to varied farm conditions. At present it must be admitted that the buyer is expected to pay for some of the work of experimenting with them. A farmer must expect to do this for some years yet. We think it will pay this farmer to try out a tractor on his farm. He should not pay for a machine until he has tried it long enough to understand what it will do under the usual conditions of soil and climate in his neighborhood. If he can find a machine in this way which will prove reasonably successful it will pay him.

THE MOON AND THE WEATHER.

IN regard to the article on page 903 entitled: "The Moon and Weather Changes," it seems to me that most people consider the weather as a local matter, and do not realize that it is a part of great air movements extending many thousand miles over the earth's surface. The cause of the different varieties of weather which we experience is the movement of areas of high and low atmospheric pressure. These areas move approximately from west to east, areas of low pressure being accompanied by unsettled or stormy weather, and those of high pressure by fair weather. Warm and cold waves are also caused by these same areas, those of high pressure being usually attended by cool weather and those of low pressure by warm weather. Within the boundaries of the United States there are frequently two or three centers of low pressure and stormy weather, and at the same time a similar number of centers of high pressure and fair weather. Such being the case how could such different varieties of weather prevailing in different sections of the country at the same time be caused by the moon? For example, how could fair weather in New England, rain in the Mississippi Valley, fair weather in the Rocky Mountain region and rain again upon the Pacific coast occuring simultaneously be explained by a change of the moon's phases? When New England has been experiencing some of the severe droughts of recent years the Gulf States have at the same time been receiving an excessive amount of rain. Both regions have, of course, been under the same lunar influence (if such influence existed) but with the widest variation in weather.

I have heard people speak of the moon driving a thunder shower "around to the north," naively assuming that the moon was a purely local affair that did not exist "up north." I have kept a daily record of the weather for 24 years and have thus had an opportunity to test many of the so-called "weather signs." In the early years of my record I gave attention to this matter of the moon's influence, using Herschel's table of the moon's changes and the various proverbs which I had heard relating to the matter, and came to the conclusion that absolutely nothing could be determined from that source. I think that any person who has the daily weather maps of the Weather Bureau available for examination and who will give them a careful and intelligent study will be forced to the conclusion that the changes of the weather cannot be ascribed to the moon or other heavenly bodies. A. B. ROBERTS.
Connecticut.

THE happy time of apple sauce and baked apple has come again. Baked sweet apple and milk is too good for the average King.

SPRING OR FALL SEEDING.

Some Experiences of a Maine Farmer.

GRASS seeding in late Summer or early Fall has but a short time to make good, and however even the catch, makes its start the next year in soil that is compact and hard, as with us. both April and May are likely to be dry and cold. Clover cannot be sown with it, as it winter-kills, and if added in the Spring, has a cold dry surface already occupied to start in. Sowing with grain, as early in Spring as the ground can be well worked, after Fall plowing, I seldom fail to get a good clover catch, succeeded by fine Timothy and Red-top.

But, as one man overpastures his fields, and proves that all pasturing is disastrous, while another pastures moderately, and keeps his meadows in good condition, so one man sows an excess of grain, and both loses his catch, and exhausts his land too quickly. Four bushels of oats to the acre is too much. I sow about two, and seldom fail to have, in the rather tall stubble I leave, a splendid growth of clover, which so protects the surface that the almost daily freezes and thaws of March and April have little effect upon it. The yield of oats is light—25 to 30 bushels—but the grain is heavy, and the many fine crops of Timothy and Red-top following are more profitable than a heavy crop of grain, and lighter hay. I sow half a bushel per acre of this mixture; a bushel of Timothy, 12 pounds of Red clover, eight of Alsike, and five of Red-top, lightly harrowed, or preferably put in with a horse rake or a plank drag, which also smoothes the ground.

Last year, all conditions being favorable for Summer seeding a piece of land which had been very thoroughly worked, I sowed the usual amount of seed, including clover, early in August, as an experiment, and having in mind the reported excellence of the Cowhorn turnip, I sowed about half an acre of it with this. As the turnips came up, they were greedily eaten by our poultry, which has free range, and only an occasional plant escaped, except a strip about 10 feet wide across one end, which the hens apparently hadn't time to finish. It was a disappointment, but this Spring I recovered from it, because where the hens took the turnips, there was a fine stand of grass, and on the narrow strip, none at all—it had been completely smothered. As no clover was in sight, I sowed it with clover alone, being the second clover seeding. Now, after haying, there is little clover to be seen. This confirms my opinion that Spring seeding with grain is the safer method for me. G. S. PAINE.

Kennebec Co., Maine.

ALFALFA AND SOIL FERTILITY.

WITH reference to the article by J. H. Reisner on pages 757-8, Mr. Reisner assumes that Alfalfa takes all its nitrogen from the air. Experiments and observations prove that this claim is too extravagant. It has been shown that Alfalfa will take its nitrogen from the soil if that element is in abundance, rather than obtaining it from the air. The attack of the nodule-forming bacteria on the Alfalfa root is identical with the infection of any other fungus on a plant. The bacterium really makes a sore on the plant, where it forms a nodule (which is simply a house for it to live in).

It is common observation that Alfalfa plants growing near a manure pile have a great many less nodules on their roots than have those which are growing in poorer soil. On one particular occasion I remember when this fact was demonstrated very forcibly. A neighbor wanted to get some soil from an old Alfalfa field to inoculate the soil in a new field which he was seeding. He drove into the field, and noticing that the Alfalfa plants near an old straw stack were much more vigorous than those in other parts of the field, he prepared to get his soil there. When the turf was shoveled off he was surprised to find very few nodules upon the plant roots. This was an eye-opener, and after digging in several places in the field, he found that the largest number of nodules and hence the best soil to sow for inoculation purposes was found where the Alfalfa growth was the sparest. It seems that where plant food is scanty, the Alfalfa plant must coöperate with the nodule-forming bacteria in order to exist, while if the soil is filled with an abundance of nitrogenous food, the Alfalfa can and does get along without the nodule-former.

ALFALFA IN THE EAST.—The claim that Alfalfa will prove profitable everywhere in the East is a doubtful one. There is no question but that it is a wonderful crop. In fact, I know of a little piece of ground in Alfalfa at the Michigan Experiment Station that gave four cuttings last season, the sum of the average lengths of each cutting being 9½ feet and making a yield of something like six tons per acre. This is big, but it is not proof that Alfalfa should be grown everywhere, although I may state that the ground upon which this Alfalfa grew was but little better than blow sand, and had not been fertilized recently. Where the conditions are such that a seeding of Alfalfa may be had without too much expense in labor and money, it may profitably be grown, but upon some of the Eastern soils which are highly acid in character, and where large amounts of lime must be applied in order to raise Alfalfa, it would not be policy to undertake it. We do know that corn is acid-tolerant, and the advice of the editor on page 766, where he says, "Plant corn! Plant corn!" cannot be improved upon, especially if your soil is very sour. I. J. MATHEWS.

LOOKING ACROSS THE BLACKBERRY FIELD. FIG. 428.

THE NEW METHOD OF GROWING BLACKBERRIES. FIG. 429.

COMFORTABLE DAYS AT CULTIVATING. FIG. 430.

GRAIN BAG AS FIRE EXTINGUISHER.

IN a dry Summer those whose fields adjoin a line of railroad are constantly menaced by the danger of fire running through the stubble, or even destroying standing crops. For whipping out a fire a wet grain bag has everything I have ever seen tried, "beaten to a frazzle." This method was learned in the short grass country, years ago, at a time when we burned miles of firebreaks each Fall to save Winter pasturage for the cattle. Grasping the bag by one end and swinging it overhead the free end comes down well flattened out, and the broad, moist surface blots out a good strip at every blow. A solid grain bag (a bran sack is too light), wetted every few minutes, is heavy enough to swing well and come down with a good whack. When the fire is simply brushed out or stamped out it breaks out again and again, and it takes lively work to get ahead of the creeping flames. The moistened bag discourages the fire from starting again where it has been beaten out and makes one's blows count for something.

One needs to "step lively" at such a time and make every blow count. It is usually impossible to work in front of a fire in standing crops and one has to make a flank attack, following up the sides until the head of the fire is overtaken. But in stubble one can whip out the very point of the advancing fire and then work back along the sides. The railroad people have urged farmers to maintain firebreaks along the railroad right-of-way. Having noticed that several fires running through a Timothy meadow stopped at a border of a field of Alfalfa, the idea of living firebreak suggested itself, and I am now trying to get a four-rod strip of Alfalfa established along my railroad boundary.

Monroe Co., N. Y. GEO. ARNOLD.

AGRICULTURAL EDUCATION.

SIR HORACE PLUNKETT, in his address at Dublin to the American Commission of Agriculture, said: "Today you have this paradox—you have provided education and useful information for your farmers in a degree and of a quality which cannot be surpassed in any European country. Yet American agriculture, by the test of the yield of the staple crops, is the least productive to be found in any civilized country except Russia." R. H.

There are two or three things to be said about that. A large share of this education and useful knowledge has never been filtered down to the people who most need it. Too many of our agricultural teachers lack the power to make their science practically available. Like most other forms of education it is getting to be considered something of a luxury for certain higher classes of farmers For 20 years the majority of our farm teachers could not see the absurdity of telling a man how to grow two blades of grass when he could not get a fair share of the price of one blade. Again, many of the average figures of crop yields are deceptive. This is a great country and an "average" covers a very wide range of territory. For example, take the oat crop. The average in the cooler climate of New England is over 30 bushels, while in the Southern States it goes to 10 or less. With wheat the more favorable localities go 20 bushels or more, while the Southern States fall to seven or less. Thus an "average" of this great country will be low because it will include figures from large areas where that particular crop is grown at a loss. Some of these critics like to talk "averages" about this great country. Yet we can take them to large areas in the Eastern States where yields and incomes are as high as any in Europe!

"WHEN the boy first takes the hoe in hand, see that the lower hand is thumb down. Otherwise he will never have the right grasp to use it efficiently," says E. F. D.

Spraying and Care of Mixed Orchard.

I HAVE about 20 peach trees, 10 cherry, 12 apple, only about one-fourth of which are in bearing this year. I wish to spray at the proper time. Will you give me necessary information? The orchard is in grass, on a gentle southern slope, and the soil is a sandy loam lying about 1,200 feet above sea level. I would like to know what should be done to make this orchard do its best next year. Peach trees are about 10 years old, and some are interlocking with the apple trees, now about eight years old, and three in bearing. The latter have a mass of foliage like wild trees, as the former owner had been ill for several years. How about plowing this orchard, and if so, when? C. D. B.
Connellsville, Pa.

It is now too late to spray these trees for any of the diseases or insect enemies, unless it might be some very late ones, that would help them this year. Spraying is a complicated job and covers a wide range of troubles, and should be thoroughly studied out before the next year's work is begun. As there are many publications that give detailed directions that may be obtained from the State Experiment Station, at State College Pennsylvania, and of the United States Department of Agriculture at Washington, they should be obtained and studied first of all. The sod should be turned over with a plow this Fall, and the ground sown to rye, which should be plowed under next Spring, and the soil kept well stirred all of the next growing season. As the peach trees are "interlocking with the apple trees," my advice is to dig them out or cut them back very severely. Evidently the trees are crowding each other, and the apple trees are suffering. If they are to be expected to flourish and bear well they must have room and good tillage or they cannot do it. H. E. VAN DEMAN.

Grafting Peaches.

I HAVE 200 peach trees from seed planted last Spring, 2½ to 3½ feet high, and now growing. I may not get them budded this Summer. Can I cut them off near the ground next Spring and graft the same as apples? I have a neighbor who grafted a peach last Spring that bore one fruit. What per cent. of seedling peach will be likely to come true to parent? I. W. B.
Rodeo, N. M.

These peach seedlings should be budded this year, if possible, before the growing season is over. If this cannot be done it is possible to graft them next Spring, but not with much hope of good results. Peach trees are not grafted with much success, so far as I have ever tried it or known of its being tried. In some climates it *may be done* in a practical way, *but I doubt it.* If it is tried the method I would follow would be to cut the scions about February, and store them in damp sphagnum moss and keep them very cool until the stocks begin to start, then graft by the bark method. H. E. VAN DEMAN.

A Potato-bug Destroyer.

I SEND a crude representation of a bug in this locality; it seems to be a species of squash bug. It is black trimmed with orange, and feeds upon potato bugs. It sticks its beak into them and sucks the life out of them. What do you know about them? A. D.
Howell, Mich.

The bug referred to in the foregoing letter may be called the potato-bug destroyer, for it lives very largely, at least, by devouring the worst enemy of Irish potatoes in this country, namely, the common Colorado potato bettle. We first found this predaceous bug (Perillus bioculatus) in New York in 1911. It had been known before in the Western States, and is apparently working its way eastward and probably will eventually spread over the whole territory now covered by the potato beetle. This bug is a welcome guest, for it is an efficient aid in checking this old enemy of the potato. It devours both the young grubs and the full grown beetles. Each bug will eat three or four grubs a day. It is an axiom that the forces of nature will ultimately establish an equilibrium. That is, no one plant or animal can long remain in the ascendency. Other plants or animals will eventually crowd out or devour the one that is dominant. When the Colorado potato beetle first began its eastward march in the sixties and seventies it created as much talk and consternation as the advent of the Mexican cotton boll-weevil has done in the South. Nowadays we think little of the potato beetle, and it is gradually being held in check and forced back into its normal proportions by its enemies. Welcome to all the bugs that will help us in our fights against our insect enemies!
GLENN W. HERRICK.

A Correction.

In my letter quoted at bottom of page 923 I am made to say 70 *cents* per tree. This should be *cuts*, not cents. I work by the hour and charge 30 cents per hour. I have been working on five-year-old Duchess apple trees and pruned 266 trees in 8½ hours—less than one cent per tree.
R B G.

CROP REPORTS.

July 31.—Up to this date Warwick County is experiencing another dry year, the worst in its history, and as a result all crops, except wheat, are being affected. Corn is almost burned up in some sections; no oats nor early potatoes. Tobacco, of which there was a large acreage put out, is badly damaged. Eggs, 14; butter, 14; fowls, 11; Spring chickens, 14; wheat, 80; corn, 85. R. S. K.
Boonville, Ind.

July 25.—Wheat, Turkey red, 68 per bushel; oats, 27; barley, 35; flax, $1.57; hogs, $7.25 per cwt.; Spring chickens, 15 cents a pound; butter fat, 22; butter, 25; eggs, 20; potatoes, 60; cherries, $2.25, case of 24 pints; currants, $2.25, case 24 pints; apples, early Summer varieties, $1 a bushel; onions, 75 to $1 per cwt. Sheep, dressed, 8 to 10 cents a pound; cattle, dressed, 10 to 12.
Columbus, Mont. W. D. J.

August 1.—Good strawberries sold from $4 at start of season down to $2.50 at close; black raspberries, $3 to $4.50 here at home, but I shipped the balance of my berries to Detroit and most of them sold for $4 per bushel. Red raspberries, $4 to $5 per bushel. Potatoes, 75 to $1; Harvest apples, $1. Cattle, best steers, $7.25; live weight; veal, $9; milch cows, $50 to $150. The creameries are paying 25 cents for butter fat. Wheat, oats, corn, potatoes and sugar beets are the staple crops, also hay. Hay, fair crop, wheat and oats a bumper crop, with the outlook for bumper crops in all other lines. New wheat is bringing at the elevators $21; oats, 32. Army worm just broke out in this county but doing little damage as yet. G. W. W.
Otisville, Mich.

July 30.—We have had very fine haying and harvesting weather. Both hay and wheat have been secured in fine condition. Wheat has been a heavy crop; one who has thrashed his crop, reports a yield of 48 bushels average on 45 acres, a pretty big story. Clover hay was light, while Timothy has been heavy as a rule. Alfalfa made a good growth. Our second crop has just been put in, in very fine shape. Buyers are offering $12 per ton for hay baled. Millers are paying 70 cents per bushel for new wheat. Corn is making a rank growth, and potatoes are doing finely. Oats and barley are doing well and will soon be ripe. Small fruits have been a good crop except strawberries. Gooseberries and currants have been good. Sour cherries were a very heavy crop. Plums seem to hang well, while Bartlett pears are a failure. Apples in this section are a good crop. Butter, 20; eggs, 21; potatoes, $1 per bushel.
Canandaigua, N. Y. E. T. B.

August 1.—We here in the central part of Missouri are having a destructive drought and very hot weather. There is no speck of green in the pastures; when cattle walk over it raises dust. Water is scarce and often hauled for quite a distance. There was no hay to speak of, and cattle must be fed as in late Fall or Winter. Corn will be a failure unless we have a soaking rain very early, which would help some of the latest planted. The plants of strawberries are mostly all dried out and everything is in bad shape. Garden stuff very scarce; out of five plantings of beans the first was picked over just once. Where to get feed for stock for the coming Winter is a puzzle, more so as we must now feed already, and only in August. But what gets me is when some salaried State or Government professor lets loose some articles which are gladly taken up by the big papers, saying there is no drought "with proper working no damage will result, the crops are no failures, etc." In many cases this is nothing but back-porch prophecy, and does not give true conditions. Glad to say that the north and south part of Missouri are in good condition to give a fair crop. C. P.
Jefferson City, Mo.

TOMMY was throwing stones, and his mother caught him at it. "Don't let me catch you throwing stones any more," she cautioned him. "Well, what will I do when the other fellows throw them at me?" demanded Tommy. "Just come and tell me." "Tell you!" he exclaimed. "Why, you couldn't hit the broad side of a barn!"—Everybody's.

Thinning Wealthy Apples.

EXPERTS in orcharding advise thinning of apples to distance of four to six inches apart. Is this wide spacing advisable with the Wealthy apple? To remove so many would take three-fourths of the fruit from my Wealthy trees this season. E. F. D.
Billerica, Mass.

While it might seem wasteful to take off more than half the apples on a tree while they are growing it is certainly profitable to do so if the tree is overloaded. Wealthy is one of the varieties that is apt to set far more fruit than can be brought to good size, and the removal of one-half or more of it when small will generally pay well. If there is from four to six inches between the apples they will grow enough higger to make up for the lack of numbers. In actual weight there is little difference between the fruit at maturity on a tree that has been thinned in this way and one that was left to carry an overload. And when we consider the serious effects on future crops and the impaired vigor of the tree from allowing it to overbear there is no reason why the thinning should not be done. Even a little experience will give one a better idea of the benefit of thinning growing fruit than a lot of verbal or written advice. H. E. VAN DEMAN.

Pruning Quinces; Driving Away Bats.

THIS Spring I set a small quince orchard, and on account of the locust probability was warned not to cut back the trees at planting. The locust has come and gone, doing no damage to those trees. All the authorities at my hand say quinces should be pruned to an "inner bud." As the natural tendency of the quince is to grow somewhat to the center I am puzzled to understand why this tendency will not be promoted by pruning to an inner bud and thus making a congested and tangled cluster of branches in the center of the tree, the branches crossing each other in hopeless confusion. I know of no quince orchard near me where I can get assistance, and I am therefore appealing to you. 2. My home is an old-fashioned brick house, and I find myself annoyed with bats, which no effort of mine has been able to overcome. Can you suggest anything?
Wellston, O. R. E. K.

1. Quince trees do not need to be constantly pruned "to an inner bud," or in any other way that will cause them to grow compactly. The different varieties have forms or habits of tree that vary in some degree, but they generally make rather bushy tops if not trained differently. They need the same common sense used in their training that anything else needs, and the judgment of the owner should be used without any fancy notions. The branches should be low and trained so as to shade the trunk and make a fairly open head. Some of the inner branches will need cutting out when they are small and here and there one that is too rampant will need heading in.

2. As to what to do to keep bats away I cannot tell, for I never had much to do with them. They like dark places in which to to spend the daytime, and if they cannot have access to such places it would seem that they would go where they could find them.

H. E. VAN DEMAN.

Florida Peaches and Cherries.

COULD you tell me whether cherries would grow well in this part of Florida? Which are the best peaches for this sort of land? Will buckwheat grow here? Which is the best chicken feed to grow here? F. L.

Any and all parts of Florida are unsuitable for cherries because it is too warm a climate. Cherries, like other northern fruits need a cool season when they are dormant as well as a warm one when they are growing. Florida is rather far south for growing peaches, but there are varieties that are quite well suited there, especially those of the South China type. The nurseries of Florida have these varieties to sell and it would be well to get some of their catalogues and select the kinds that are recommended for the most southern sections. The Angel, Jewell, Imperial Hall, Bidwell, Dorothy and Luber are among those that should he planted. Buckwheat is a crop that requires a cool climate and will not do well in Florida. One of the best things to grow for feeding to chickens is the cowpea. It is well adapted to a warm region and yields a lot of pods that are filled with peas. Another tropical plant that is grown in south Florida and the West Indies is known as pigeon pea. It makes a sort of bush and bears pods that contain peas that are much liked by chickens. H. E. VAN DEMAN.

LEGAL QUESTIONS.

Hunting Privileges.

A LOCAL real estate agent called on me today saying he was requested by the Arden Hunt Club to obtain permission from the farmers of this vicinity to cross their farms and to have the privilege to send their carpenters ahead to build fences or rails to cross with their animals, etc. What would you do if placed in this position? Would it be likely, in any way, to interfere with rights or title in the future? No written consent given or asked. A. L. P.
New York.

It would certainly he advisable in this case to have a written understanding of the privileges which the Hunt Club is to obtain, which privileges should be revocable by the farmer at any time on giving notice, and should contain a provision for the payment by the club of all damages occasioned to the farm. This should clearly define the rights of both parties and would give the Hunt Club no rights which could not be terminated by notice or which would interfere with the title to the property.

Railroad Must Maintain Fence.

COULD yon advise me regarding the division line of railroads? The railroad company's property cuts through ours, and we have to cross their tracks to reach our barns. The fence they erected years ago is entirely gone, and some time ago I applied to the Department of Maintenance for another, stating I wished them to erect a woven wire fence to keep children from the tracks. Are they (the railroad) not obliged safely to fence their property, and what steps can I take should they put me off indefinitely?
New York. H. C. F.

Unless you or your grantor have received compensation for fencing along the railroad or have agreed to build and maintain a lawful fence along said line, the railroad company is obliged to erect and thereafter maintain fences on the sides of its road, of height and strength sufficient to prevent cattle, horses, sheep and hogs from going upon its road from the adjacent lands, with farm crossings with gates therein whenever and wherever reasonably necessary for the use of the owners, and so long as such fences are not made nor kept in good repair, the railroad shall he liable for all damages done to any domestic animals on the road. This fence shall not be of harbed wire. It may be that you could compel the railroad in proceedings in equity to build the fence, but this is an expensive proceeding, and the best procedure for you would be to complain to the Public Service Commission of the Second Department at Albany. M. D.

Public Nuisance.

A CHEESE factory is located up the road from my residence about 10 rods. They allow the excess whey, etc., to run down the ditch, along the roadside, past my house. This ditch is fairly filled with flies and other insects. We realize that it is a great breeding place for germs of various kinds. To whom can I make complaint so as to compel these factory people to dispose of their surplus whey in some other manner? I wish to avoid a lawsuit, for that is too expensive. My property here has cost me over $10,000 in cash, and this factory nuisance is of great damage as well as very dangerous, in the way of fever and other diseases. F. J. K.
New York.

You should make a complaint to the town Board of Health or the town Health Officer. The Board of Health is empowered to make such orders and regulations for the suppression of nuisances and concerning all other matters which in its judgment seem detrimental to the public health in special or individual cases, and serve copies of the orders upon the owner or occupant of any premises whereon such nuisances or other matters may exist. If the orders are not complied with, the Board or its servants may enter upon the premises to which such order relates and suppress or remove such nuisance. [Sections 21 and 31 of the Public Health Law.] M. D.

The Sun's Heat for Power.

SOME years ago we had a discussion of the use of sun heat in producing power. There were two general methods, neither of which proved entirely satisfactory. In one case a collection of mirrors were so arranged on a shaft that their combined reflection of the sun's rays were thrown upon a small boiler at the center of a large wheel. This wheel revolved or changed its position so as constantly to receive the sunlight. Every school boy knows how by concentrating light in this way with a mirror, or a bright piece of tin, he can cause an intense heat which will burn flesh, or even set fire to cloth or wood. In the Far West, where there is but little cold and rain, this method of utilizing the sun's rays would seem to be possible, yet after thorough trial the work was declared to be not much more than a scientific toy. Considerable time was required to get up steam in the boiler, and while some power was developed, the cost of the apparatus and other considerations put it out of competition with steam or gasoline power.

Another plan was tried on a small scale in New Jersey, and later on a much larger scale in Egypt. In this plan a device very much like a hotbed was selected, with double glass sash, and a series of iron pipes filled with water inside. All gardeners know what a heat is created inside the average hotbed on sunny days, with the top closed. In the experiments with this device, the water in the pipes was raised to boiling heat under the glass when the sun was hot, and this boiling water was used to run an engine for pumping and similar purposes. The only trouble was that this heat was only developed during a part of each sunny day, and, of course, the engine stood still on cloudy or rainy days. The device is now operating in Egypt, in a region where the sun shines most of the time, and is said to be giving quite fair results in that country for pumping and similar purposes. The Experiment Station of Arizona is now coming back with the proposition and thinks it entirely within the range of possibility, that within the next few years the sun will be employed practically for pumping and generating electricity. A new instrument called a recording pyrheliometer has been installed at the University of Arizona. This measures and records the energy given off by the sun. The object is to ascertain the amount of the sun's energy that is available for work, at pumping or driving a wheel. In connection with this knowledge of the amount of energy available from sun heat, several new types of sun motors have been devised. They are too costly now to permit their general use, but we should judge from the report that several of them at least are practical, and can develop considerable horse power. The proposition is made for the State of Arizona or one of the other arid States to offer a prize of $100,000 to the man who will first solve the problem of practically handling the energy of the sun. The arid States could well afford to give 10 times that sum, if they could obtain a machine to work by sun power, which was anywhere near as practical as windmills which handle the power of the wind so effectively. We believe that this problem will sooner or later be worked out, and that without question the sunshine of the Western States will be put to effective use in doing such work as pumping, generating electricity, or any other work which requires the turning of a wheel.

WANT TO KNOW.

QUACK GRASS IN ORCHARD.—Last Fall we plowed a piece of old meadow and planted a small orchard This Spring the land is covered with a heavy growth of quack grass. How can this be killed without injuring the trees? W. M. J.
Buffalo, N. Y.

BOBBY: Ma, you said that I shouldn't eat that piece of cake in the pantry—that it would make me sick. Mother: Yes, Bobby. Bobby (convincingly): But, ma, it hasn't made me sick.—Credit Lost.

"I HAVEN'T seen Pilkington for a week." "No; he hasn't been out of the house since his accident." "Was he seriously injured?" "No, but he feels the disgrace deeply." "Disgrace?" "Yes. After living in a city all his life, he went into the country, and was run over by a milk-cart!"—London Farm and Home.

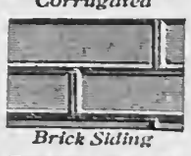
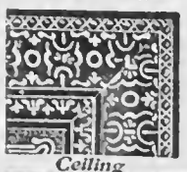
Lowest Prices Ever Made On World's Best Roofing

Edwards Patent "Grip Lock"

Corrugated


Brick Siding


Ceiling

Lightning-proof, Fire-proof, Rust-proof, Rot-proof, Galvanized Steel Roofing Lasts as Long as Building Stands
Once you have purchased and laid Edwards Tightcote Galvanized Steel Roofing your roofing expense for that building is at an end.
Its cost per square is the lowest ever made. It has *no* up-keep cost. Always beautiful in appearance. Reducing cost of insurance.
EDWARDS Exclusive Tightcote Process
Makes Rust-Proof Roofing. The zinc spelter becomes practically one piece with the steel. No ordinary galvanizing can compare with it. Each and every Edwards Metal Shingle, Metal Spanish Tile, each sheet of Edwards Reo Steel Shingles, Grip Lock Roofing, Pressed Standing Seam or Roll Roofing, Ceiling, Siding, etc., is dipped in a bath of molten zinc, one at a time, after the metal has been stamped and resquared. The edges are galvanized as heavily as the sides. Not the space of a pin-point on steel exposed to weather.
How To Test Galvanizing Take a piece of any other galvanized steel, bend it back and forth several times, hammering it down each time. You will then be able to flake off great scales of the galvanizing with your finger nail. Apply this test to a piece of Edwards Tightcote Galvanized Steel Roofing—you'll find no flaking.
EDWARDS Patent Interlocking Device
Prevents Warping, Buckling or Breaking, Protects Nail Holes—they can't Leak or Rust. Nails are driven through the under layer not exposed to weather—cannot rust. No special tools or experience needed to lay this Roofing; anyone can do the work—lay over old shingles if you wish.
Reo Steel Shingles *Cost Less, Outwears 3 Ordinary Roofs* and are your joy and pride forever. No matter what kind of a building you have in mind there is a style of EDWARDS Galvanized Roofing exactly suited to your needs.
FREIGHT PAID Lowest Factory Prices
Greatest roofing proposition ever made. We sell you direct—*save you in-between dealers' profits.* No matter what your building is, we simply ask the right to prove to you that our prices are lowest ever made for World's Best Roofing. Postal or coupon brings Roofing Book No. 873.

EVENTS OF THE WEEK.

DOMESTIC.—The New York Stock Exchange, the last big exchange in the world to remain open in the face of a general European war, closed its doors July 31 for the first time since the panic of 1873. The Consolidated Exchange, the Cotton Exchange and the Curb quickly followed. The flood of selling orders by foreign security holders precipitated the action. Four failures were announced, two houses being members of the Stock Exchange and two of the Cotton Exchange.

The Interstate Commerce Commission, in a divided opinion, August 1, in the 5 per cent. freight rate increase, denied all advance of rates to the railroads between the Buffalo-Pittsburgh line and the Atlantic, including the New England and the trunk line freight territories, and allowed the 5 per cent. increase to the roads in the Central Freight Association territory, between the Buffalo-Pittsburgh line and the Mississippi River, except on certain commodities, such as coal, coke, iron ore, cement, brick, tile, clay, starch and plaster. The commission disallowed all increase of lake-and-rail routes and of rates between the Central Freight Association territory and other portions of the Official Classification territory. The commission suggests to the railways in the New England and the trunk line territories that they may increase their net incomes by abolishing various types of service now given to shippers without charge. Of the rates in the Central Association territory, the commission declares that they are not only lower than those in either of the other territories, but lower than those in any otl r section of the United States. The commission suggests that all railroads in the Official Classification territory examine carefully their freight rates, rules and regulations with a view to increasing rates found clearly unremunerative and modifying burdensome rules and regulations. The railroads which applied for the commission's permission to raise their freight rates 5 per cent. were the fifty-two lines east of the Mississippi and north of the Ohio and Potomac rivers. They asked for a 10 per cent. increase in 1910, and it was refused. Railroad managers contended that in the last three years the roads spent $600,000,000 in new capital, bnt that in 1913 the earnings were $16,000,000 less than in 1912; that higher wages, taxes and new investments caused the increase in expenses; that the New York Central was forced to lay off 23,000 men since September, 1913, and unless relief was granted government ownership of railroads might follow. Opposing contentions were that the railroads were constantly getting higher revenues; that they spent more on improvements last year than ever before in history; that one terminal cost $108,000,000; and, above all, that free service to big industrial concerns approximated in value $30,000,000 a year.

To protect the gold supply of the country Secretary William McAdoo announced at midnight August 2, that $100,000,000 of emergency currency will be issued to the banks of New York. At the same time he announced that emergency money would also be issued to banks in other parts of the country under the Aldrich-Vreeland law.

The city of Kingston, Jamaica, was shaken by an earthquake of terrific violence August 3. The shock was of greater intensity than that of 1907, which practically destroyed the city and suburbs. The disastrous circular motion of the previous seismic disturbance was absent, however, on the present occasion, and so far as is known no lives were lost and no great damage resulted. Some damage was done in Port Antonio and several other towns.

To prevent a raid upon the gold supply of the United States by international banking houses that had built up foreign credits totalling $85,000,000 within the past fortnight, the New York Clearing House, August 3, voted for the issue of Clearing House certificates. The action means the suspension of specie payments except under the supervision of the Clearing House, and is directed toward the conserving of the strong financial condition now existing by preventing the projected drain of our gold to Europe. New York savings banks put into force the requirement of sixty days' notice of withdrawals, but fixed weekly maximums of $100 or $50 that might be withdrawn without notice. Similar requirements were put into effect in Minneapolis, St. Louis, Memphis, Cincinnati, Cleveland, and New Orleans.

WASHINGTON.—Plans for the relief of Americans marooned in Europe were formally announced August 4. The United States cruiser Tennessee sailed from New York August 5 with $5,000,000 to $8,000,000 in gold and twenty-five army officers, who will superintend relief measures in Europe. Ships to carry Americans home will follow as fast as the War Department can procure them. Germany notified the State Department that no foreigners in that country will be permitted to leave during the mobilization. France may pursue a similar course. President Wilson sent another message to Congress asking for $2,500,000 for the relief of Americans in Europe.

By a unanimous vote the House, August 3, passed the Underwood bill prepared by Administration officials, providing for the admission to American registry of foreign built ships. The bill is designed to relieve as far as possible the tie-up in American commerce by the complications in Europe.

August 3 the House and Senate passed a bill removing technical restrictions on the issuance of $500,000,000 of reserve currency. President Wilson appealed to the people not to become alarmed, as this country was well prepared to withstand any financial crisis. The President was successful in his appeal to avert a tie-up in Western railroad traffic. The Senate voted to authorize the Secretary of the Navy to establish naval lines to carry passengers, mail and freight to South America and Europe. President Wilson summoned Senators Gallinger, Smoot and Brandegee, Republican leaders, to ask their aid in expediting all legislation so that Congress might adjourn at an early date and relieve uncertainty about pending anti-trust measnres.

August 5 President Wilson decided to place naval officers as censors at all wireless stations, to insure neutrality. There are foreign stations at Sayville, L. I., and Tuckerton, N. J.

SENDING MONEY ABROAD.—Sending money to relatives and friends marooned by the war in Europe is a simple procedure. Explaiued August 4 by Wilbur J. Carr, chief of the consular service, this is the "how": Send to the State Department a certified check, draft or postal money order payable to "Chief, Burean of Accounts, State Department." State plainly the name of the person (full name), city and address, if any, abroad. The money will be cabled immediately to the nearest American consul, who will issue local currency or a draft (United States warrant) upon the State Department, payable to the payee, who calls at the consulate.

THE EUROPEAN WAR.—The German Emperor declared war on Russia August 1, and August 2 began an invasion of France without waiting for a formal declaration of war. August 4 Germany declared war on Great Britain, three hours before the British Parliament made a declaration of war. The same day Germany declared war on Belgium, which had refused permission to violate Belgian neutrality, and began bombarding two important Belgian cities, Liege and Namur. The Germans have crossed into Swiss territory, which is neutral, the three German armies now invadiug France, entering by way of Basle, Switzerland, the Duchy of Luxemburg, and Arlon, Belgium. The three armies are said to comprise 1,000,000 meu, and in each case they have crossed ueutral territory to enter France. The Germans were repelled by the French at Petit Croix, near the Swiss frontier, August 3. German warships bombarded the Russian port of Libau, on the Baltic, August 3. All Europe is now in arms. On the one hand Austria-Hungary and Germany are opposed by Russia, France and Great Britain, Servia and Montenegro. Italy has declared her neutrality, but is mobilizing. Belgium, Holland and Switzerland have mobilized. The German demand that the Belgian government should permit the free passage of German troops through Belgium was answered by hasty preparations to resist such an advance across Belgian territory. Sweden has made no answer to inquiries from Russia and Germany as regards her attitude, but is preparing to defend ner neutrality. Japan is making ready to live up to her alliance with Great Britain in case of certain eventualities. Spain is reported to be preparing a proclamation of neutrality.

The British House of Commons has voted $525,000,000 for "emergency" purposes. A bill was introduced in the German Reichstag asking for an appropriation of $1,250,000,000 for the expenses of the war.

Germany, Great Britaiu, France and Austria have asked the United States to represent them in the warring capitals. On August 4 President Wilson issued a strong declaration of neutrality. There were reports August 4 that the Germans were entering Dutch territory, though the Netherlands had announced neutrality. Up to August 4, the Servians were repelling Anstrian invasion. August 4-5 German forces were repulsed in Belgium with heavy loss. August 6 Austria-Hungary declared war on Russia.

DEATH OF MRS. WILSON.—Mrs. Woodrow Wilson, wife of the President, died in the White House August 6. Her death resulted from Bright's disease, from which she had been a sufferer since she came to the White House. This trouble had been recently aggravated by a general nervous breakdown which began when she was injured by a fall on the marble floor of the White House in February and was accelerated by the strenuous social season and overexertiou in social betterment work and other humanitarian endeavors. Mrs. Ellen Louise Axson Wilson, wife of the twenty-eighth President of the United States, was born in Savannah, Ga., fifty years ago and in that city spent her childhood and her early girlhood. She was married to Mr. Wilson June 24, 1885. Like her husband, Mrs. Wilson was the child of a Presbyterian minister and also the granddaughter of one. Her parents were the Rev. Samuel Edward Axson and Margaret Jane (Hoyt) Axson. The Rev. and Mrs. Axson lived first in Madison, and then for a number of years in Rome, Ga., where the Rev. Mr. Axson had a church. Mrs. Wilson's earliest education was acquired in Savannah, and later she atteuded the Woman's College in Rome, Ga.

HE: "I suppose you think I'm a perfect idiot?" She: "Oh, dear, no; we're none of us perfect."—London Mail.

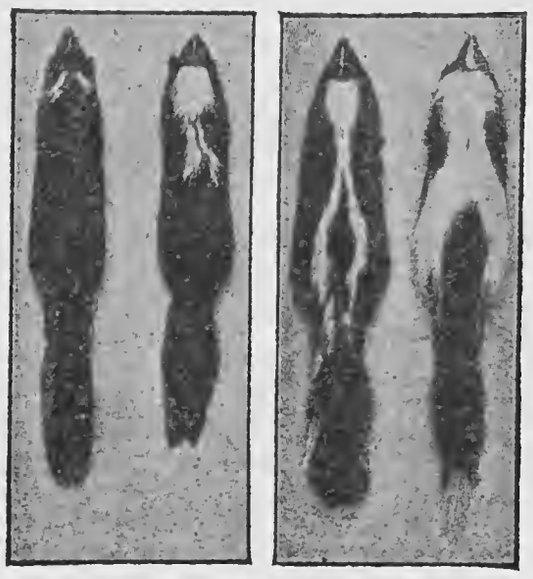
The Value of the Skunk.

FARMER'S Bulletin 587 deals with the "economie value of the skunk." A man who has buried a suit of Sunday clothes—the result of a chieken house encounter with one of these animals—on his return from evening church, is likely to feel doubtful about the economic value of the skunk, but robbing henroosts is practically his only vice. His virtues are the destruction of great quantities of insects, particularly white grubs, and the value of his hide as fur.

There are nine distinet species of large skunks and eight sub-species, 15 forms occurring in the United States. Of the lit-



COMMERCIAL GRADES OF SKUNK. Fig. 432.

tle spotted skunks found in the West, there are 14 species and six races, the smallest being the pygmy skunk of Mexico, only 9½ inches in length.

In northern climates skunks go through a partial hibernation in very cold weather. In Spring they pair and usually breed but onee a year. The young, litters running from six to 12, are born with eyes closed, like kittens, and require about six months to get full size.

To get a fair idea of what the skunk eats, 62 were killed at different times of the year, and the contents of their stomaehs carefully analyzed. Grasshoppers, crickets, beetles and their larvæ formed a large proportion of their food. Fifteen had eaten rats, mice, ground squirrels and pocket gophers; three carrion; three lizards and salamanders; three erawfish; two fungi; two earthworms; six berries or other fruit. One stomach had the feather of a bird; one, parts of a domestic fowl. Two contained eentipedes; one, sawflies; one, eicadas; and another the stem of a sueculent plant. The insects

SKIN PROPERLY "CASED." Fig. 433.

eaten were mainly of injurious types. In New Mexico, during an invasion of range caterpillars, skunks were abundant, and investigation showed that 60 to 95 per cent. of their food was the pupa of this insect. In 1887 the Nebraska agricultural authorities reported that skunks were eating the Colorado potato beetle. The small spotted skunks are great destroyers of rats and mice, and are sometimes domesticated for this purpose.

Skunks are now protected by law in 13 States. Open seasons are as follows: Maine, November 1-Mareh 1; New Hampshire, October 15-April 1; Vermont, November 1-May 1; New York, November 1-April 15; Delaware, December 1-March 10; Ohio, November 15-February 1; New Jersey, November 1-February 1; Indiana, Illinois and Michigan, November 1-April 1; Missouri, November 1-February 1; Kansas, November 15-March 15. The first protection secured was in parts of New York State 20 years ago, when the hop growers found that the skunk was active in destroying the grub or borer that worked at the base of the plant.

Of late skunk has been one of the most popular furs, 13,400,000 skins having been sold during the eight years ending with 1913. The value ranges from 25 cents to upwards of $2. The picture, Fig. 123, shows four commercial grades of skunk skins. No. 1, from left to right, is nearly all blaek, bringing the highest price; No. 2 is short stripe; No. 3, narrow stripe; and No. 4, broad stripe, the poorest from the furriers point of view. Northern skins are usually of finer quality and the black more intense than those from southern localities.

Skunk skins should be "cased" for market as shown in Fig. 433, and the following directions for skinning observed: Begin with the middle of the hind foot and with a sharp knife slit up the rear edge of the leg to the under side of the tail, being careful not to cut into the scent glands. Then cut the opposite leg in the same manner. No other cuts in the body of the animal are necessary. Cut around the heel of the feet and turn the skin back over the body. Strip the skin from the tail bone with the help of a split stick grasped in the hand while the thumb presses firmly against the back of the animal just above the tail. Continue to turn the skin baek over the body, using the knife only when neeessary to cut ligaments. Care should always be taken to cut around the nose, mouth, and eyes to avoid tearing the skin.

THE MAIL BAG.

Frost-proof Potato Cellar.

WE are putting a cement ceiling in a potato cellar. Is there any way to make it frost and damp proof?
Six Lakes, Mich. J. S.

I know of no way of making conerete frost-proof except through insulation by means of hollow walls, but there are waterproofing compositions which may be obtained through dealers in builders' and masons' supplies whieh would doubtless answer your purpose. If your local dealer cannot supply you, application to any of the cement manufacturing companies would bring information as to where your needs could be met. M. B. D.

Contaminated Water.

WHAT ean be done to clear the water in a driven well, 36 feet in depth?

A six-ineh heavy wrought iron pipe was used as casing, in which is a 1¼-inch galvanized suction pipe to within three feet of bottom. The well was driven in July, 1913, but thus far we have been unable to use the water on account of the taste of oil and rust. The water is clear and cold when first pumped, but after standing a short time turns to a rusty color and shows oily at the top. We made the mistake of using plain black pipe for the casing instead of galvanized, but a poreh is now built over the well and this pipe cannot be easily removed. I have tried roek salt, also charcoal, and have also pumped the well out on several oceasions, but without much improvement. B. A. L.
No. Tonawanda, N. Y.

You have evidently been unfortunate in striking a vein of water charged with mineral matter of an objectionable nature and the product of decomposed vegetable matter whieh gives it the oily appearance upon standing. I can offer no suggestions as to any method of improving this vein of water but it may be practicable to drill deeper and reach another source of supply which will be free from the impurities of this one. The pipe used is not responsible for the trouble and if a year's use of the well has not freed the water from its objectionable features it will probably be useless to expect good water from that source.
M. B. D.

Strawberries After Potatoes.

I HAVE a patch of strawberries about four years old. I wish to have a new patch next Summer. When is the best time to transplant the new patch, which is in potatoes this year? A. P.

At any time up to the middle of September, provided the ground is moist, you can set new plants. They will not give a full crop next year, but will begin bearing. We should dig the potatoes as soon as they are fit, put the ground in shape and set ont plants while the soil is moist.

Trimming Big Privet Hedge.

AT onr Summer home here we have a splendid privet hedge which needs trimming, but unfortunately it was not kept cut back as it should have been, and now it will be neeessary to saw off the top of it, as the trimming shears would not be strong enough for the work. Do you advise, under the cireumstances just mentioned, cutting it back during the Summer, or waiting until the Fall?
Brooklyn, N. Y. T. L. C.

It will not injure this hedge in the least to cut it back now. In fact this is a very favorable time for doing so, as the seeond flow of sap is just starting. Privet is one plant that shearing or cutting at anytime of year, no matter how severely it may be done, never seems to injure. It is one of the grossest feeders in existence, and its recuperative powers are almost unlimited. K.

Cistern Filter.

HOW is a brick filter built for a cistern? What kind of briek and size, ete.? J. I. H.

Ordinarily unglazed red brick is used to filter cistern water, a simple wall being built across the cistern to divide it into two compartments, the larger of whieh receives the water from the roofs and the smaller the filtered water that has passed through the pores of the bricks. I am unable to say how permanent these brick filters are, though they have been in quite common use in this vicinity; it would seem as though the pores of the bricks would become filled in a comparatively short time and render them useless for this purpose. Very likely the length of time that they would serve would depend largely upon the amount of fine dirt held in suspension in the water as it came from the roofs.
M. B. D.

Experience With Peat Muck.

LAST Spring I had occasion to write you of a piece of peat muek I have on my farm. Apparently the heavy growth of briars has done it a world of good. I have a magnifieent stand of corn, where 20 years ago positively nothing would ever grow. Advice given by you was to keep manure off. I did so on most of it. I placed some there, and also gave a good coating of air-slaked lime, and a liberal coat of muriate of potash as advised. Surely all this ought to make corn and apparently it will; growth about twice as large as where nothing was applied. Yet some years ago an oat crop was thrashed and straw left to decay, also a barrel of lime had been placed on the straw to hasten decay. Right there was a heavy coat of Blue grass, a real stiff sod, and when I plowed same appeared like leather as it came loose from peat muck underneath. While I believe that the briar root growth has done more for me than all else, yet lime and potash show good results. B. M.
Ligonier, Ind.

Hope Farm Notes

THE CONNECTICUT POULTRY MEETING.

PART I.

A CROWD.—It is something like climbing a rocky road up Zion's hill to reach the little country church at the Connecticut Agricultural College. Nestling among the higher hills the church stands on a rocky ledge as if the original worshippers desired the deeper soil for more practical purposes. Mansfield Center, the nearby village, was settled in 1692, so this church is 150 years old, at least. Originally a larger building, it was rebuilt—smaller to suit the dwindling congregation. Strange how the factories of New England have grown larger and larger to suit expanding trade, while the churches have worked the other way. Yet the things which have given true strength and character to New England came out of the churches rather than the factories. There must have been some great gatherings in this old church in years gone by. Take the time when the news from Lexington was brought into this section. Only a few miles north of here old Israel Putnam left his oxen for the women folks to unyoke and rode off to battle. What a sermon the minister of this church must have preached. Then you have only to glance at the little flags fluttering over the graves in the country churchyard to imagine what a congregation toiled up the hill into this church when Lincoln called for volunteers! If the old church could speak what stories it could tell, and yet I doubt if it ever had more people than were packed into and around it on the night of July 29. The Connecticut Poultry Association had come home to roost, and without realizing it was making a part of that peaceful history which is to substitute the hen for the eagle on the American flag.

CROWDED QUARTERS.—It had been one of those cold, cheerless days which bring out the best and the meanest qualities of New England like a thick ham sandwich. Furious bursts of driving rain had washed the green hills. Now and then the sun would wipe away the tears and smile for a moment so that even old-timers were deceived into getting away from cover—only to be drenched. Looking over the rolling country the hills seemed like great unhappy animals, drenched through the skin and humped up in discomfort. Night closed in starless and black, with a cold drizzle of rain. As the darkness fell people came from all directions—walking out of the shadows to secure an early seat. They crowded the pews beyond the limit and gave themselves hardly half the space they allotted to a hen. They packed the gallery like sardines, filled the aisles and stood up at the back. The choir seats and the platform were crowded, and the standees looked with speculative eyes at the organ as a possible roosting place. Outside a double row of late comers peered in through the windows. Surely the star of the evening who was to address such a gathering might well say that he "played to full capacity." And the "star," plain Tom Barron, sitting on that crowded platform, had evidently began to wish he had never come inside the crowded church.

A HENMAN'S MESSAGE.—That was what it was all about. The master hen builder had come from England to tell how he makes an egg-laying machine. At the egg-laying contests in Connecticut, Pennsylvania, Minnesota, British Columbia and New Zealand the English birds had been laying rings around the others, and here was the master builder where the critics and the curious were to corner him if they could. It was a critical crowd, bristling with "show me," for it hurts your average hen man to admit that anyone can tell him about a hen. Right up in the deacon's pew sat our old friend, "Mapes the hen man," like a bird dog on the scent of a statement which opposed his conviction. Up where the choir usually made harmony sat that wise old veteran, A. F. Hunter—hero of a hundred battles. D. J. Lambert, Judge Card, Whitney, Prof. Graham, McGrew, and dozens of others who have for years directed poultry thought, were there with sharpened pencils and a shade more or less of prejudice against this new idea of making egg-laying machines. For within rifle shot of where they sat at the egg-laying contest was the unanswerable argument that "a hen's a hen for all that," without regard to her comb or wattles or tail feathers or other "fancy" points. Before the meeting I asked many of these men what they thought of Barron and his hens. The answer invariably was:

"The hens are all right. As for Barron I do not know—I came here to find out."

And up where the minister usually dignifies the chair sat Tom Barron. He knew he had an audience of cold-blooded critics full of pet theories and spurs. He acted like a man who would gladly be at home with 3,000 miles of salt water between himself and his audience. But out at the egg-contest houses 10 Leghorns and 10 Wyandottes were calmly sleeping with head under wing, after making a convincing speech on eggs. It was now up to their master to say a few words!

"Tom Barron!" The name "Tom" fits him like his skin. No one would ever think of calling him Thomas, unless possibly Mrs. Barron had some strong family admonition to communicate. You may have pictured some typical "John Bull"—thick, heavy and solid, with side whiskers and curling hair. Your mental picture is all wrong. If ever a man looked like an alert, well-bred Leghorn rooster Tom Barron is the man. Erect, alert, active, with long legs, compact body, black, straight hair, kindly eyes and a long prominent nose, it seemed to me as I studied him that the plastic part of Tom Barron's personality had gone into the trap-nest along with his birds. Through these long years of culling out the drones, he has put himself through a test of instinct and intelligence which has given him something of the sterling characteristics of the business Leghorn. It is true that a man cannot excel as a poultry keeper unless he is half hen. Barron is all hen or as near to it as a human can get. No higher compliment could be given. History shows how the British lion came growling over here years ago. This very old church sent out some of the men and some of the spirit which twisted his tail and sent him home. Now come the British Wyandottes and Leghorns to beat us at the peaceful battle of the trap-nest. In this same old church were the men who must learn how to beat the British hen as their ancestors handled the lion!

A PLAIN TALK.—These Connecticut hen men do not waste any time in getting on the nest. I have been at meetings where some word-spouting orator took half an hour to "welcome" the crowd, while another consumed as much time in response. President Beach, of the Agricultural College took possibly five minutes to tell the company to make themselves at home. Then Mr. Brundage took three minutes to say we were on hand. Then he introduced Tom Barron. There was not much applause for here was a gathering of "show me" people. They waited and reserved judgment. Mr. Barron is about the best hen builder in the world, but he is no orator, and it is his happy privilege to recognize the fact and admit it. He stood first on one foot and then on the other. He didn't know what to do with his hands. Happily they are big and strong, and scarred and hardened by work. Now and then he dropped an h or two, and like an economical Englishman he tacked them on at some more convenient place. He was just plain "Tom" Barron talking of what he had to say brightly, sincerely and simply as if he were sitting down and talking to a friend. I think this was what held and captured his hearers. Had he been a skilled orator, a polished speaker, most of those who listened would have felt that somehow he did not quite touch their business. They would have felt that Barron might be the "talker" of the family, but that Mrs. Barron or someone else was really responsible for those 20 hens out at the contest. These practical men came to know that up on the platform, trying to "tell about it," they too would shift from one foot to the other, and most likely forget the important things they wanted to say. Here was a plain man like themselves who talked about the common things they could all understand.

THE IMPORTANT THINGS.—Mr. Barron talked and showed pictures of his English hen plant for over an hour. Then he answered questions. Some of these were from people who make an effort to be "funny" and stagger a little under the burden. Barron made much of his use of the trap-nest, and this seemed to get on the nerves of some of his critics. They asked him if he trap-nested his cows, or if this English yacht which is coming over to race has been trap-nested! Barron took it all good-naturedly, and many of his replies pleased the people greatly. It was easy to see by this time what the dominant thought of this meeting was to be. Every poultry keeper knows that he feeds both drones and workers in his flock. The drone will eat as much as the worker, but the latter must not only pay a profit on her own food, but also pay the fare for her lazy sister. The great problem therefore is to cull out the drones before they get a chance at our feed. Is there any way of doing this with certainty, and can we improve our flocks by breeding improved stock as surely as we can improve a dairy herd by introducing new blood? The "standard" score card and the so-called contests at the poultry shows are of no value whatever in answering such a question. You and I may have a dairy of cows. The home and all it stands for may depend on our ability to increase the amount of butter per cow. We know what to do! Go and buy a Jersey or Guernsey bull of some "prepotent" family and put him at the head of our herd. If we can select a bull with a long line of ancestors noted for their dairy records, we are practically sure to raise a lot of heifers capable of beating their mother at butter production. We may accept that fact as demonstrated. Now can we do the same thing with our hens? If not why not? There you have the vital question in practical poultry culture. I do not wonder that the fanciers fly at Tom Barron, for the message of breeding and selecting which he brings is destined to make their "scale of points" look like a farce and a useless thing. Barron claims that through a long series of trap-nested females he secures males as prepotent and strong to transmit their mother's good qualities as the well-bred bull. I shall test his theory by obtaining one of his finest cockerels and breeding him to my "scrubs" next season. But this is away from our text. The next morning I saw Tom Barron in a more natural role of orator. This time he stood upon the housetops. Upon the roof of one of the henhouses at the poultry contest, Barron, with a hen in his hands, was showing how he cast out the drones, while hundreds of hen men gathered around to watch. But let us take that up next week. H. W. C.

Fertilizer for Strawberries.

I HAVE about two acres of land planted to corn, oats and potatoes. Next Spring I intend to plant strawberries on the same; before doing so I shall sow it down to rye and plow it under next Spring. I should like to buy my fertilizer and mix it myself this Winter. Could you inform me what would be best and about how much I should require; also the best way of applying the same? Could you inform me as to about the necessary number of plants it would require for two acres, the rows being four feet apart?

Rockland, Mass. D. R.

Your plan of seeding the potato land to rye for plowing under next Spring is good. After plowing under be sure to pack the rye down firmly. Then make the surface soil fine and set out the plants. If you wish to mix the chemicals we should use 400 pounds dried blood, 400 pounds sulphate of potash and 1,200 pounds acid phosphate to be used on the two acres. The best results for us have come from scattering the chemicals at the time of setting on a two-foot strip, where the plants are to go. Work it in well by running the cultivator back and forth. We shall set the plants two feet apart in the row. If the rows are four feet apart this will mean about 5,500 plants to the acre.

Wild Carrots.

WILL the Hope Farm man tells us if there is any merit in the wild carrot? It certainly has some good qualities, not the least of which is tenacity. I have been fighting it for many years and the end is not yet. One of the merits of the clover plant, according to many writers, is the amount of vegetable left in the soil by decaying roots. Is this not true of the carrot? Another good quality is productiveness or reproduction. The plants may be cut off time after time and in a few days you find another set of blossom or seed heads, each time with a shorter stem, saving its time here in order to ripen its crop of seed. If some of our plant wizards could in some way graft this quality into the Timothy plant he would certainly be the means of reducing the "high cost of living" in horses and cows. E. J. L.

Let us not wait for these "plant wizards" to "whiz" these qualities into Timothy. It is about as likely to happen as the report that they crossed the milkweed on the strawberry and grew berries and cream on the same plant! With us the wild carrot makes a fair quality of hay. Our horses are fond of it—particularly the older ones. This year there is a smaller crop than usual of wild carrot. Without doubt the root does open the soil and provide considerable organic matter.

EASTERN MASSACHUSETTS CROP NOTES

This has been so far a very peculiar season. While perhaps no more rain than is needed has fallen, yet it has been distributed over many days, as the rule a little each day, or at least, every other day, and to finish gathering the hay crop is a problem. Dog days started in about three weeks before their time, and bid fair to continue. Those that pushed their haying along early were lucky, and almost everyone reports a good crop, or better than last season. Corn is looking well, but is in most cases very backward and small, and unless frost holds off well will not probably be a full crop or mature properly. Potatoes on the contrary never looked better, and certainly promise a good crop if looks are worth anything. The past few weeks have been good growing and farming weather for them. Onions also look well, and if they bottom up well, will be a large crop. Various kinds of raspberries have turned out well, but picking weather has been bad, and many have dropped off the bushes. Prices have been low on these and currants, and other small fruits also. Apples now look like a good crop, especially the earlier varieties, some trees of which are loaded, in fact, too many on trees to insure best size. The Winter fruit hangs about right to turn out a good crop of fair-sized fruit. Insect pests have been and are now very troublesome, and will affect the quality of much of the fruit, except that which has received extra care, and this will probably pay those who were able properly to spray their fruit a good profit for so doing. Pears are a light crop in many cases. Cranberries now promise a good extra crop, but the next few weeks may change the outlook. A late Spring followed by a cool Summer, especially nights, has not been altogether favorable to most crops especially corn, and unless a fairly late Fall without serious early frosts helps us out we will not feel we have had a favored season. Strawberries, which promised a large crop early in the season, were seriously affected by the early dry spell, and in some towns were a very short crop or no crop at all. Blueberries, which last year in this section were a heavy crop, in fact the heaviest ever known about here by reason of the big forest fire a few years before, are way below the average this year, and many disappointed seekers go home with nearly empty pails. Wild grapes are not fruiting well this season, and will be short of the demand. Walnuts and chestnuts look like a good promise of a crop. A. E. P.

July 28.—The Peninsula Horticultural Society will hold its next meeting in Wilmington in January, when it expects to make its biggest and best exhibition of fruits, vegetables and home-canned goods, eclipsing, if possible, the fine display at Easton last Winter. Prizes amounting to $1,500 will be given, $300 in three prizes for the best general exhibit of fruit, $25 for the best single box of apples, $25 for the best five boxes, and $50 for the best 10 boxes of apples, with second and third prizes in each class. Every good commercial variety will be recognized in box packs, and $8 will be allotted to each variety, amounting to $200 in all for this class. Prizes for vegetables will be larger and more numerous than ever before, and home-canned goods will receive suitable recognition for the first time. There will be a prize of $15 for the best exhibit of canned fruits and vegetables canned by a housekeeper, $15 for the best exhibit of fruits canned by mother and daughters, the team work prize of $15 for the best exhibit of tomatoes by girls in the canning clubs. The Summer meeting of the Peninsula Horticultural Society will be held at Mulberry Hill orchard near Easton during August. All the fruit growers everywhere have been invited. Lunch will be served by the orchard owners assisted by the county Grange. Automobile trips will be made to surrounding orchards and other places of interest. Approximately 12,000,000 quarts of strawberries were carried by the Delaware Railroad during the berry season. This shipment falls below that of last year, and is ascribed to the drought. It is estimated that 100,000 hampers of apples have been shipped to market during the last fortnight. Wheat thrashing is almost over. Some phenomenal yields of wheat have been reported. Many claim to have received a yield of 30 bushels per acre, others 40, and some even as high as 50 bushels to the acre. We are having plenty of rain now, which has greatly benefited growing crops, but is delaying wheat thrashing where it has not already been thrashed. A severe hail storm visited some portions of this county on July 25, almost totally destroying growing corn, tomatoes and fruit. C. H.

Dover, Del.

The Home Acre.

NOTES FROM A MARYLAND GARDEN.

I OFTEN wonder whether our Northern friends have the bother with crab grass (Panicum sanguinale) that we have here and southward. It never gets too dry for the crab grass, but of course it flourishes more with favorable weather. You may hoe it out, but if you do not rake it out it catches hold of the soil again and is smiling and happy in a few days, and clean it all out well, and in a day or so you will find a young crop starting and if now cultivated down at once will soon be as strong as ever. Where tomatoes are let tumble on the ground, and cultivation has to stop, the crab grass soon gets higher than the tomatoes, so that it is absolutely necessary in the gardens to train the tomatoes up so that the grass can be kept down.

Earliana tomatoes have been plentiful since late June, but the John Baer, now the last week in July, is just beginning to ripen a few. It seems to be identical with Chalk's Jewell, except that it is later. And yet we were told that it would make ripe fruit in 30 days after setting good plants. Mine were strong plants, started in the greenhouse and spotted out in frames and were set in the open ground the last of April, and did not show a ripe tomato till the 16th of July. I paid a dollar for a packet of the seed, and have that now charged to experience. The Brimmer, a big tomato of the Ponderosa type, has been giving some very fine fruit, and is much smoother than Ponderosa. My late tomatoes to come in just ahead of frost have now been set. These are mainly Globe, and I find the Globe excellent outside, while it is now largely grown under glass too.

My plot of 2,000 Gladioli is now in full glory. Niagara is not white as claimed, but a very pale canary color, and as I have it beside the Blue Jay the contrast is very pretty. I get a few of the best Groff mixtures every season, and am sure to find some fine ones in the lot, which I propagate to themselves. One crimson with a white blot on the lower petals bloomed this year flowers as large as Princeps. Then there was an exact counterpart of America, but with a taller and longer spike, and not so closely packed flowers as those of America. Sulphur King is a good yellow, but very slow to increase. Eucharis is the best nearly white of any I have. Heliotrope is a better purple than Blue Jay, in fact almost a navy blue, and about as near blue as will probably ever be found in the Gladiolus. For cutting there is nothing better than the compactly arranged flowers of America.

One plant in my shrubbery border that attracts most attention now is the Bignonia grandiflora, the Chinese trumpet flower. Trained up by the side of the porch it is now covered with its great heads of big orange-colored flowers. This plant is grafted on our native B. radicans, and I have to keep the sprouts cut out, but it seeds freely, and I have this Spring raised over 100 seedling plants from last year's seed, and as it is a pure species there is no doubt that the plants will be true to type.

A row of Meehan's Marvel mallows, planted to hide an ugly board fence, is now as tall as the fence and flaunting its great blooms of crimson, pink and white, each flower almost as large as a dinner plate. Like the morning-glories, they close up in the evening. They make a fine background to a bed of perennial Phlox of various colors, of which I have 250 plants in 11 varieties growing in nursery rows, and now making a mass of bloom.

The Cardinal climber, a cross between the cypress vine and the scarlet morning-glory, is now covering a wire fence 50 feet long with its pretty cut leaves, and brilliant scarlet flowers. These too close in the afternoon, but the plant is a rampant grower and the foliage is handsome. Unlike the morning-glory and the quamoclit, its parents, it makes very few seeds, and one has to watch very closely to get any. Last year this same fence was covered with moonflowers which made a wonderful display, and to my surprise I find this season many volunteer moonflower plants from seed dropped and left all Winter. This suggests the idea that it may be best to plant the hard seed of the moonflower in the late Fall, and I will try it. W. F. MASSEY.

Maryland.

ASPARAGUS FOR HOME USE.

WILL you tell me about setting out and caring for an asparagus bed in the family garden? Would a mulch grown in the Fall on the bed be good for a cover, and what would you recommend? B. M.

Washington, R. I.

PLANTING.—Asparagus being a hardy perennial, of long life, lasting under favorable conditions 20 years or more, it pays to give special attention to the preparation of the soil where it is to remain permanently. The bed should receive an application of two or three inches of well-rotted manure and be either spaded or plowed in as deeply as possible, mixing the manure with the soil as thoroughly as it can be done, and in addition a liberal quantity of raw bone meal may be used in the furrow at time of planting with considerable advantage. On account of the soft spongy nature of the roots and their tendency to decay when bruised or broken in the Fall, it is not considered good practice by most of the successful growers to plant asparagus at that time, as almost invariably much of the planting is lost through root decay in the Winter following, whereas the Spring-set plants seldom if ever are lost from this cause. The planting may be successfully done any time in Spring from the time the ground is in condition to work up to the time growth starts, but the sooner it is planted after the ground is in good condition for working the better the results. When planted in a small way for private use, and particularly when it is necessary to economize on ground space, plant in beds or strips, say six feet wide in which three rows are to be planted, a row on each side about 12 inches from the edge and one in the middle of the bed, setting the plants 12 to 14 inches apart in the row. When the plants are set care should be taken to spread the roots out so that the soil may be easily worked in among them, covering the crowns about three inches deep. By going over the bed every few days with a steel rake, we destroy germinating weeds and keep the beds clean until the sprouts appear above ground, when hoe cultivation will be necessary. If two beds or more are made running parallel to each other, walks 24 to 30 inches wide should be left between them. This method of culture is of course only suitable for the production of green asparagus. When white sprouts are desired the plants should be set in rows three feet apart and 12 to 14 inches apart in the row. This distance between the rows will be sufficient to admit of ridging. Good clean cultivation is necessary during the growing season and should in no wise be neglected if good grass is to be grown.

FERTILIZING.—This is quite important, and for the best results must be applied twice each season, early in the Spring and at the close of the cutting season, and may be varied with great benefit to the plants. I find that a good coat of fine well-rotted manure applied in early Spring and worked into the soil with a spading fork (care being taken not to injure the crowns of the plants), and a coat of raw bone meal applied at the rate of half a ton to the acre and worked into the soil at the close of the cutting season, will give most excellent results. This method of manuring supplies the plants with all the manurial constituents they need for vigor and the production of first-class sprouts.

WINTER PROTECTION.—While the asparagus is perfectly hardy in nearly all sections, yet where the ground freezes deeply, it will be quite a benefit to the plants if thy recive a mulching of forest leaves or strawy manure at the beginning of Winter, the plants will go through the Winter in better condition and start earlier and with greater vigor in the Spring than if they have no protection. This mulching should be removed early so that the Spring fertilizing may be done before growth starts. K.

White Ants in Flower Beds.

CAN you tell me how to destroy white ants that infest my flower beds? Last year they destroyed my geraniums. This year the geraniums were unmolested but they attack the pansies nearby. The ants work up through the center of the stalk, sometimes cutting them off like a cutworm; they come about the first week in June and are gone by the middle of July. M. V. C.

Seymour, Conn.

The species of white ants that occur in this country are blind and live within decaying logs, stumps, and roots and occasionally in the woody stems of living plants, like geraniums and nursery trees. In every case in which the author has observed these insects injuring living plants he has found them abundant in the near vicinity in decaying wood of some kind. Moreover, when the decaying wood that served as the home of the ants was removed, they quit injuring the living plants. I venture the opinion with a good deal of confidence that M. V. C. will find some decaying log, stump, roots, rails, or other pieces of wood near or in the garden in which the white ants have found a home and from which they have migrated and have become troublesome to the geraniums. If these pieces of wood are removed the trouble will soon cease.

GLENN W. HERRICK.

Machine for Barn Thrashing.

WHICH will give the best satisfaction for barn thrashing, a separator with wind stacker and self-feeder, or one fed by hand, with raddle carrier?

Jamestown, N. Y. N. B.

I would advise that you use a self-feeder and wind stacker. The wind stacker will place straw almost anywhere within the building with little assistance from a pitchfork. The air separates straw, dirt and grain, so that the operator knows just how well the riddles are working by the amount of grain thrown out of the stacker. In the old belt stackers the grain was so mixed with straw that its presence could not be detected; but the heavy growth of young plants around the base of the pile bore eloquent testimony to its presence. L. E. HAZEN.

REGROUND FERTILIZERS.—On page 852 D. A. R., Florence, Mass., complains of lumps in nitrate of soda and potash. In placing his order he should order the goods reground, which I always do, and have no trouble along this line.

Cheshire Co., N. H. T. J. F.

IRRITABLE OLD MAN: "Say, does this car always make this racket?" Chauffeur: "No, sir; only when it's running."

"FROM the way you are staring at me, madame, I conclude I look like some one you know." "So you do. You remind me so much of my dear old English bull terrier."—Baltimore American.

Hardwood Ashes BEST FERTILIZER IN USE. GEO. L. MUNROE & SONS, Oswego, N. Y.

ROCK PHOSPHATE PRODUCED

25 bu. Wheat at a cost of $2.40
9 T. Silage " " " " 3.20
2½ T. Clover " " " " 3.20

In each case more than three-fourths of the Phosphorus remained in the soil and gave increased yields in the future crops.

DAYBREAK ROCK PHOSPHATE

260 pounds Phosphorus per ton
Ground 95% through 10,000 mesh screen.

Will pay you big profits, and build up the fertility of your soil.

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York

HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.01, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 75 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

WE have had many requests for information as to building a good vegetable cellar. The greatest trouble seems to be over ventilation. It seems that conditions of climate, soil and convenience vary so that general rules are not of great value. We would like reports from people who have operated such cellars successfully. Tell us how you would make another to improve upon any you have seen.

*

THE country storekeeper has many troubles, and earns most of the money he gets. What I object to is the method of charging cash customers with the interest on investment, bookkeeping, and frequent losses from the credit customers' accounts. The mail order house enables the cash payers to put into their pockets what would otherwise go to the "slow pays" and dead beats. In a discussion with three merchants in a neighboring town two admitted that they could sell for 10 per cent. less if all sales were for cash, and the third said that the figure would be between five and 10. D.

There is pretty much the whole thing. It will be hard to convince me that it is my duty to pay my neighbor's bills or the interest on them. Yet that is what I do when I pay cash promptly at most country stores. The price charged is large enough to cover losses from bad debts or delayed payments. Merchants have often admitted this. None of them will be likely to deny it if you offer cash and ask for a fair discount on their prices. In their own buying they know they can do better when paying cash.

*

ON page 948 we suggested that two kinds of station bulletins might be issued—one of a popular nature written by practical and successful farmers. Some of our station workers do not seem to take kindly to the suggestion. We meant it merely as a constructive criticism and we think the plan worth a trial. Some of our scientific men do not seem to realize the wide gulf which stretches between their knowledge and the thought of busy farmers. A reader in a Western State sends us an important question—and writes:

I have sent to the Experiment Station of this State, but their answer, which I enclose, is so patched up that I have no faith in it, thinking it was done by the office boy.

The answer is sound and accurate but written in scientific or "class room" language so that the farmer may well be excused for not understanding it. The agricultural scientist will tell you that his chief work should be "research." We might suggest that the careful search of a good old volume will reveal the following:

"Thou thyself art a guide to the blind, a light of them which are in darkness."

*

LET us talk to you once more about the danger of signing contracts or leases which you do not understand. Some people rarely read over a paper before signing it. Later they find that they have bound themselves to impossible conditions. We have a case where a man in the West signed a five-year contract to pay $50 a month for a farm in New Jersey. This man knew nothing about the farm, and when he moved on found that he could not possibly make a living on it. Hardly a week passes without a letter from some one who has signed a paper he did not understand and now finds himself tied to a hard bargain. In the majority of these cases there was no good reason why these papers ever should have been signed without an investigation. On the other hand trouble usually comes when two people agree to do a certain thing in partnership, but have no papers at all to show what the agreement is. Trusting to memory in such cases is a sure introduction to trouble. The safe way is to have some good lawyer draw up an agreement which both parties understand, and have both sign it.

I UNDERSTAND you have stated that all wealth in this country came from the farmers. Where is your proof for such a ridiculous statement, when we all know that the cities contain most of the nation's wealth? S. J. K.

What we have said and what we repeat is that every cent's worth of property upon which this great city wealth is based came originally out of the land. It was produced by farmer, miner and forester! If our friend thinks otherwise we challenge him to name any legitimate form of wealth which is not originally based upon some crop or mined product. Let him take up the burden of proof. He ought to be able to do this easily if, as he says, the statement is ridiculous. Come forward and show us some form of wealth which did not originally come out of the soil. No wonder the wealth of the land is accumulating in town and city when 65 cents of each consumer's dollar goes to the handlers who may mostly be classed as city men. In addition to this a good share of the farmer's 35 cents also goes back to the city to pay interest and other similar expenses. This unequal division of the dollar, received through many years for farm and mine products, is what piles up the city's wealth. We wait with interest for our friend to name the wealth which did not originally come from the land.

*

THE European war is too young to have had much definite effect on prices of farm products. Usually, war, with its consequent waste and stoppage of production, increases all prices of what we consider necessities. At the first intimation of war speculators here advanced wheat prices 10 to 15 cents per bushel, and other grains in less proportion. But in this case all of the great ship-owning nations are involved and afraid to use their merchant ships for commerce, lest they be seized as prizes by the enemy. So grain prices dropped to nearly their former level, but are now advancing again on the probability of some ships being transferred to the American Flag and others guarded by armed escorts on the way across. Europe needs our surplus grain, and will have it if there are any ships to carry it.

Fifty million bushels of wheat are tied up at American seaboard points. With cotton growers the situation is more serious. The crop is large and the industries using our raw material in England and Germany, paralyzed or nearly so. Cotton speculators have it in their power to squeeze planters who must sell at once to a very low figure, unless, as is intimated, the Government takes some means to protect the planters.

Fruit growers on the Pacific Coast are alarmed at the outlook, as they depend on Europe to take a large amount of their finest apples, as well as some other fruits. Dairy and poultry products are but little affected yet, except the item of imported cheese, which goes to a limited trade. The cheese market in Canada, where exports are heavy, is upset. Our potato crop is so large that the stoppage of possible European shipments is not likely to be noticeable. Refined sugar is up one-half cent, the German supply of beet sugar being cut off. Beans have advanced upwards of $1 per hundred, and flour is 50 cents or more per barrel higher. Of course it is to be hoped that the trouble will soon pass over and the world be spared the deplorable weariness and burden of industrial and financial exhaustion, and the grief of the "widows and fatherless" always resultant from a long war.

*

THE farmers of Southern New Jersey greatly need a bridge across the Delaware River so that produce can be hauled direct to Philadelphia. The present system of ferry transportation is slow and out of date. What is needed is a system of quick direct transportation, so that loaded wagons may be hauled across a good bridge direct from farm to market. Such a plan would help reduce the "high cost of living" by increasing direct trade and making an easier path from producer to consumer. There should also be a similar bridge across the Hudson from New Jersey to New York City. This would enable farmers and gardeners to load a wagon or a truck at the farm and drive direct to New York for distribution. As it is, such loads must be ferried over the river—a slow and expensive method of reaching market, and one which prevents direct trade. The problem of delivering food to New York is complicated because the city is on an island, so that approaches to it are restricted. A bridge over the river would make easier shipments and also help to increase the food supply. New plans for farming would be organized, and auto-truck service would be developed for quick distribution. New land along the marshes would be brought under cultivation. Such a bridge is a necessity now and must be built in the future.

WHEN we expressed the opinion that a Wyandotte hen of the dumpling-like shape shown in the "Standard of Perfection" will not prove a heavy layer we had no idea how hard the fanciers were hit. A prolonged howl about "slandering a worthy breed" and "a rude slap" is going through the poultry press. Well gentlemen, your words will never settle it. There is one final test—that is a pen at one of the recognized egg-laying contests. It is time to stop this childish scolding. Why not play a man's part, if you believe these dumpling-shaped birds can make a heavy record, and come forward with 10 of your "ideals?" Of course you know THE R. N.-Y. is not "slandering" Wyandottes or their breeders. We are for the most useful hen that can be found, regardless of her shape. The next contest starts November 1. Will you get into it with a pen of your dumplings, or do you just want to *talk?*

*

FRESH from school, I absolutely refused to live on a farm. Then it meant to me hard work, little spending money and being deprived of all the things I considered most needed for happiness. Now I have come around to Washington's view of agriculture. More sense, considerable time spent in teaching in comfortable farm homes and regular reading of THE R. N.-Y. account for the change. E. S.

We think more and more city people are taking a sensible view of farm life and country living. At one time the "hayseed" idea predominated. Then came the "back-to-the-lander" nonsense of making a fortune on a farm, whether prepared for farming or not. Both of these have blown out, and sensible town people realize the limitations and the possibilities of the farm home. Those of us who live in the country realize that there are drawbacks and inconveniences. It is not all a world of sunshine and pleasant dreams, this living on a farm! Yet after a fair analysis and honest consideration of advantages and discomforts, we become more and more attached to farm life, and would not be separated from it.

*

IN parts of Western New York there has been a scourge of plant lice this season. Our reports indicate that nothing like it was ever known before. Many growers did not realize the serious nature of the trouble until their trees were covered and all ordinary remedies failed. We have received some criticisms of the experiment station because it has not devised or suggested a sure remedy. It must be admitted that the aphis is a difficult insect to control. It seems that last season the insect was not abundant, and as a result few orchardists sprayed, this year, as advised by the station. As a result in a season favorable to the work of plant lice the insect multiplied enormously and in many cases reached a point beyond help from sprays before fruit growers realized it. Early in May the station sent out a letter of warning, and gave the best treatment known at that time. Here is part of the advice then given:

Efforts to protect bearing apple orchards from plant lice are, as a rule, failures. These are due mostly to the manner of spraying and the lateness of making the applications. Most orchardists do not spray until the insects are abundant and the leaves are curled. Little benefit is derived from treatments under such circumstances as not many of the lice are destroyed, and besides there is always great danger that the most of the injury by the insects is done. The foliage on which the lice have been feeding becomes weakened and may prove susceptible to further injuries from spraying mixtures. Instead of waiting until injuries begin to show, the grower should spray before many of the leaves have curled and the lice have developed to formidable numbers.

Those who are inclined to criticize the station should be fair. Did they follow the advice to spray early? The present scourge of lice seems hopeless with our present knowledge, but the scientists are still working at the problem.

BREVITIES.

YOU may still seed barley for a Fall hay or fodder crop.

NOW get your eye on those pullets for the next year's layers.

CAN you not plan to run water into the house before Winter comes?

SEPTEMBER 1 is about the limit for seeding Hairy vetch north of New York.

A SWEDISH engineer has devised a scheme for burning dry powdered peat on railroad engines, which gives to the peat about 80 per cent. of the heating value of coal.

A CITY ordinance in New York prohibits the use of public watering troughs for horses. This is to prevent the spread of glanders and similar diseases. Private buckets must be used.

"DOG days" has nothing to do with dogs. "The term, borrowed from the Romans, who called Sirius, the brightest of the fixed stars, the dog-star. At one time during the Roman epoch, the rising of this star coincided with the rising of the sun in the latter part of July."

THE EUROPEAN WAR.

IT is impossible to give accurate details regarding the European war. Events travel at lightning speed, and all news from Europe is carefully censored. It seems to most of us incredible that in this age all of a sudden, so-called civilized nations should fly at each other's throats and pass back into an age of barbarism. Few of us in this country really know what the fighting is about. It may be at bottom one of those undying conflicts of race hatred, or a battle between militarism and the growth of Socialism which has been so evident of late in Europe. For centuries it has been a favorite trick of military leaders to start a "war scare," or even to provoke a war, when the common people began really to think logically about their condition.

Powerless to prevent or stop such a war, our people are interested in estimating its effect upon American conditions. Morally the effect cannot be good. One would think that the fearful loss and grief which must follow this cruel destruction of life and property would show our people the sin and folly of war. On the other hand there has always been a "war party" in our public life. This party demands a larger army and navy, and a national policy based on the actions of a boy who goes about with a chip on his shoulder seeking a fight. The European war will give such politicians a new text from which to inflame the public mind and pull it away from the study of needed reforms. It will also kindle race hatreds between those of our people who have ties of blood with the old countries.

Industrially a war in Europe will have a varied effect upon business in this country. It does not seem possible that such a gigantic struggle can last long. The cost in money is tremendous, and modern weapons are so horribly deadly that the end must come soon. Yet the enormous loss of property will be felt in all parts of the world. Vast sums of money will be taken out of circulation here and sent abroad. One reason for enforcing the 60-days limit for withdrawals from savings banks is to prevent such a drain. One branch of business which will be directly affected is the fertilizer trade. Practically all the potash used here comes from Germany. Both potash and nitrate of soda are used to some extent for making explosives and thus would probably be considered "contraband of war" and subject to capture if shipped. At first thought it would appear that if several million men stop producing and go to destroying property there will be a greater demand for the labor of those who remain at work. Upon that theory this nation ought to profit by a European war, since the market for our food and manufactured goods ought to be improved. Under the blockade sure to be established, it will be difficult to get our products into European ports, and there are comparatively few vessels left free to carry merchandise. Thus with cotton and wheat to sell we find ourselves without means of carrying our goods to market. At the opening of the Civil War this country did its share of the world's carrying trade. Our commerce was destroyed and we have depended on foreign vessels since then. This war, if prolonged, will enable us to build up our shipping industry once more. For years, following such a war, the European nations must come to us for our surplus food, while they cannot send us large quantities of manufactured goods. They must also return and sell at a low figure many American securities, such as stocks and bonds, and this will mean less money sent over each year to pay interest and other debts. In its effect upon industry the war will probably be beneficial to this country if we can remain neutral, but in its larger and final effect upon the general progress of civilization it is a curse and a menace.

FARM BUREAU WORK.—The farmers along the southern tier of counties in New York State seem to be making good use of the farm bureaus where these organizations have been started. Recently two counties in Southwestern New York united for a picnic, with over 2,000 persons present. On August 6 the Broome County Farm Improvement Association held its picnic at the county home near Binghamton. It was a pleasant day, and about 600 people came to enjoy the outing on the pleasant grounds of the home. Addresses were made by M. Quinn, president of the association; H. W. Collingwood, and E. R. Mimms, the County Advisor. It was an excellent gathering of progressive and intelligent farmers, who are giving much thought to industrial questions in their vicinity. These farmers clearly understand the economic question involved in the 35-cent dollar. They are trying to work out plans for coöperative work, which will give them more varied crops, and greater variety of work, and better market facilities. One excellent feature of the prospect in this part of New York State is the fact that these farmers realized the importance of working out their own problems in this way, without asking other classes or other industries to come and do the work for them. The situation all through this territory is very encouraging, and the outlook for farming is good.

New York Fruit Growers' Outing.

THE LAKE TRIP.—The writer was with the members of the New York State Fruit Growers' Association when they were the guests for one day of the Champlain Valley Fruit Growers' Association, and the Plattsburgh Chamber of Commerce, and can say some good words about the courtesies extended to the visiting fruit growers, in opportunities to see their beautiful lake and thriving city, and to learn about their progressive orcharding. In coming to Plattsburgh on the excursion planned by Secretary Gillett, the Western New York Fruit Growers enjoyed one of the best outing trips of their lives. They went for a good time, many of them taking their wives, the total number on the chartered train being close to 300. Their scheduled route was to leave Rochester at 1 p. m. Tuesday, arriving at Saratoga in the evening. The party was luxuriously entertained at the United States Hotel, and took their train the next morning for Lake George. A large part of the day was spent on the steamer on the lake, enjoying the scenery of perhaps the most beautiful of New York's small lakes. Leaving the lake in the afternoon the party boarded their train, and their route was along the shore of lake Champlain to Plattsburgh.

ENTERTAINMENT AT PLATTSBURGH.—The Chamber of Commerce and Fruit Growers had arranged for a steamer trip Thursday morning on Lake Champlain, and at 8:30 the members of both associations with some citizens of Plattsburgh were on the steamer. A most interesting route was taken, going up the lake on one side of its three large islands, South Hero, North Hero and the Isle of Monte, and then down on the other side close to the Vermont shore. There was a session of the two Associations held in the new High School building in Plattsburgh on returning, the main topic for discussion being the new apple grading law, which will be enforced this Fall, and about which many apple shippers have not taken pains to learn. They may not pack their apples according to its requirements, and so be ready for the inspectors whom the State Department of Agriculture may send out to inspect their shipments of apples, and there is reason to believe that the Commissioner of Agriculture will try to enforce the law.

THE NEW GRADING LAW.—It may be well to give some brief quotations from this law, as read at the meeting at Plattsburgh, followed by the expression of feeling towards it by the president of the New York State Fruit Growers' Association, L. L. Morrell.

"New York standard fancy grade or classes for apples of one variety, which are well-grown specimens, hand-picked, properly packed, of good color for the variety, normal shape, free from dirt, diseases, insect and fungus injury, bruises and other defects except such as are necessarily caused in the operation of packing.

"New York standard (A) grade shall consist of apples of one variety which are well-grown specimens, hand-picked, of good color for the variety, normal shape, practically free from dirt, diseases, insect and fungus injury, bruises and other defects except such as are necessarily caused in the operation of packing; or apples of one variety which are not more than ten per centum below the foregoing specifications, on a combination of all defects or five per centum on any single defect.

"New York standard (B) grade shall consist of apples of one variety which are well matured, hand-picked, properly packed, practically normal shape, perfectly free from dirt, diseases, insect and fungus injury, and which may be of medium or less than medium color for the variety; or apples of one variety which are not more than 10 per centum below the foregoing specifications on a combination of all defects or five per centum on any single defect.

"Apples not conforming to the foregoing specifications of grade, or, if conforming, are not branded in accordance therewith, shall be classed as unclassified and so branded. The minimum size of the fruit in the package shall also be branded upon it as hereinafter specified and in addition to the other marks hereinafter required.

"Any person who knowingly misbrands or adulterates apples within the meaning of this act, or who knowingly violates any of the provisions of this act, shall be deemed guilty of a misdemeanor and, upon conviction, shall be punished for the first offense by a fine not exceeding twenty-five dollars and not less than ten dollars; for the second offense by a fine not exceeding fifty dollars and not less than twenty-five dollars, and for the third and each subsequent offense by a fine not exceeding two hundred dollars and not less than fifty dollars, together, in all cases, with the costs of prosecution."

President Morrell did not think the enforcement of the law would be a burden to commercial apple growers, but rather a benefit. A brand on packages that is guaranteed as to class and quality mutually aids both the shipper and buyer, and there should be no need of compelling an honest pack by law. Mr. Morrell had used a private brand on his best fancy pack for years, and guarantees all fruit with this brand. It has obtained for him the best markets and profitable prices. He could see some defects in the new law, but fruit growers will now do well to coöperate with the State Department of Agriculture, that its intention to benefit all parties may be carried out.

CROP PROSPECTS.—Members from all parts of the State reported the prospects of the fruit crop in their section. Reports from the Hudson River Valley indicated that there is a large crop of apples there, probably 50% more than last year. The crop of apples in Western New York is reduced this year somewhat because it is not the bearing year for Baldwins. Most other varieties are generally bearing heavily, and probably the crop on the whole is 33% larger than last year.

CHAMPLAIN VALLEY FRUIT.—The Champlain Valley apple growers have been under the direction of their farm bureau agent, and the past year have had with them a fruit expert from Cornell University, and are working out some of the problems of the orchard very successfully. These orchardists are not trying to grow the late Winter apples very extensively. One reason is they lack cold storage facilities for handling large crops, and another is that late Fall and early Winter apples are especially adapted to Clinton County. The two that attain to the highest perfection are Famense and McIntosh Red. These, picked and shipped at once to New York and Boston sell for good prices, and as no other section of the country is growing these apples quite so well there is little danger of competition. The Champlain Valley orchardists are mostly dairy farmers, some of them beside are engaged in commercial potato growing. They say that all these together can be practiced more economically than one alone. The same teams and equipment of tools needed for one can be used for the others, with small additions. On the dairy farm the young orchard can be started with small extra cost, and a common practice is to plant the trees with the silage corn after the field has been prepared and manured for it, as about all the extra work is involved in planting the trees, as they are cultivated with little trouble.

ORCHARD AND DAIRY.—One dairy farmer the writer visited when on the auto trip makes a dairy of 40 high grade Holstein cows profitable, and also has 50 acres of apple orchards. He showed us six acres from which he had harvested 1,500 barrels of apples that sold for $3,500. The Secretary of the Champlain Valley Fruit Growers' Association also showed our party his fine orchards that were loaded with Fameuse and McIntosh apples. He had sown in them a cover crop of oats and peas, and vetch. The oats and peas he would cut for his cows and leave the vetch to grow and plow under in the Spring to fertilize the trees. One tree which he pointed out he said had produced 10 barrels of apples in one year and the profit was greater on it than on one of his cows.

ORCHARD INTER-CROPPING.—In this orchard other methods practiced which are worth considering are that no fertilizers are used but the clover intercrop, which is alternated with potatoes. When an orchard is planted potatoes may be planted for an intercrop and very thorough cultivation given both the potatoes and the trees. In this rotation the clover crop is sown the following Spring. After the clover is sown a strip of a few feet wide close to the trees is kept well cultivated, and I think all or part of the clover is left on the ground to fertilize it after being mown. By this way the cash cost of feeding the trees is mostly saved, and the potatoes largely pay expenses of maintaining the orchards before they come into full bearing.

Thursday evening the excursion party took sleeping cars for Thousand Islands where they arrived Friday morning. During the forenoon the party went for a steamer trip on the St. Lawrence River, and in the afternoon resumed their journey by rail via Richland and North Rose, where a stop of two hours gave time to see some good orchards there. The train arrived at Rochester late in the afternoon, all feeling that the excursion trip to the Champlain Valley was well worth while.

New York State News.

HYDRO-ELECTRIC BONDS.—The Up-State Public Service Commission has authorized the issue of $300,000 of the five per cent. 40-year first mortgage bonds of the Salmon River Power Company, to be sold at not less than 85, to net $255,000. This sum is needed to discharge the obligations arising out of the construction of the company's hydro-electric plant and transmission lines, not heretofore provided for, and to continue the work of construction on the plant. This makes a total bond issue for this project of $3,535,000.

THE "APPLE CAR."—The Hudson River district has not been so well cared for, heretofore, in the matter of "farm specials" as have other parts of the State. But the "apple car" begins its itinerary on August 21 at Marlborough, Ulster Park and Saugerties. It is at Coxsackie, Ravena and Albany on the 22nd; then goes down the eastern side of the river to Schodack Landing, Stuyvesant and Hudson for August 24; and reaches Germantown and Poughkeepsie on the 25th. Thence it goes to Rochester, Spencerport, Brockport, Albion for the 26th and to Medina and Lockport for the 27th. The car will then be moved to the State fair grounds where the exhibits will be unloaded. On September 7 the car will again be loaded and start on another journey being at Fulton and Oswego on that date; at Hannibal, Sodus and Red Creek on the 8th. On the 9th it will reach Williamson, Webster and Charlotte; on the 10th Hilton and Morton; on the 11th, Lyndonville and Barker and on the 12th, the last date of the itinerary, at Burt and Ransomville. The purpose of the special car is to enable the Department of Agriculture and the State College of Agriculture to give instruction in apple packing under the new law.

MILLIONAIRE ROAD WORKER.—The millionaire chairman of the State commission on prison reform, Thomas M. Osborne of Auburn, worked incognito as a laborer among prison convicts on the highway near Meridian, a short time ago. He wielded the pick and handled the shovel like one of the gang, his purpose being to gain more first hand information about the life of a convict. After the day's work was over he carried his tools to the shed and partook of the prisoners' fare that was supplied at a tenement house nearby where the convicts are confined when not at work on the roads. Mr. Osborne visited several convict camps on other days studying conditions and problems in connection with prison reform, a subject in which he is greatly interested.

EDUCATIONAL EXHIBIT FOR FAIRS.—A general agricultural exhibit has been prepared by the College of Agriculture which will be available for town and county fairs this Fall. The exhibit covers a large variety of subjects. The local fair association is required to meet one half of the cost of transportation of the exhibit and one half the expense of the person in charge. Requests for this exhibit must be made of the Department of Extension Teaching, College of Agriculture, Ithaca, N. Y.

PROCEEDINGS PUBLISHED.—The Proceedings of the 74th annual meeting of the New York State Agricultural Society have just been published by the State Department of Agriculture as Bulletin 60. It is a well printed volume of over 200 pages, illustrated, and contains the addresses and papers complete that were given at the annual meeting in January of this year.

J. W. D.

New York State Crops.

The State Department of Agriculture gives the following summary of crops:

The hay crop will not be as large as last year, but larger than the average for a term of years. Corn, wheat, rye and oats, are generally good. Small fruits are generally good, cherries, grapes and currants much larger in yield than in 1913. Peaches will show a very small crop. Apples for commercial purposes will be far below last year's crop but the local crops will be much larger.

A brief summary of crop conditions in the State at this time, based upon last year's crop as 100, is shown in the following table:

Fall apples, 129; Winter apples, 139; Baldwin apples, 127; Greening apples, 116; Bartlett pears, 61; Kieffer pears, 54; Other varieties, 69; Plums, 67; Peaches, 24; Quinces, 62; Grapes, 101; Cherries, 121; Currants, 112; Gooseberries, 95; Strawberries, 115; Potatoes, early, 106; Potatoes, late, 106; Beans, 100; Cabbage, 96; Hay, 91; Corn, 102, 102; Wheat, 99; Rye, 99; Oats, 102; Barley, 97; Buckwheat, 105; Hops, 95; Alfalfa, 105; Tobacco, 102.

Woman and the Home

From Day to Day

Midsummer.

Around this lovely valley rise
The purple hills of Paradise.

O, softly on yon banks or haze,
Her rosy face the Summer lays!

Becalmed along the azure sky,
The argosies of cloudland lie,
Whose shores, with many a shining rift,
Far off their pearl-white peaks uplift.

Through all the long midsummer day
The meadow sides are sweet with hay.
I seek the coolest sheltered seat,
Just where the field and forest meet—
Where grow the pine trees tall and bland,
The ancient oaks austere and grand,
And fringy roots and pebbles fret
The ripples of the rivulet.

I watch the mowers, as they go
Through the tall grass, a white-sleeved row
With even stroke their scythes they swing,
In tune their merry whetstones ring.
Behind the nimble youngsters run,
And toss the thick swaths in the sun.
The cattle graze, while, warm and still,
Slopes the broad pasture, basks the hill.
And bright, where Summer breezes break,
The green wheat crinkles like a lake.

The butterfly and bumblebee
Come to the pleasant woods with me;
Quickly before me runs the quail,
Her chickens skulk behind the rail;
High up the lone wood pigeon sits,
And the woodpecker pecks and flits.
Sweet woodland music sinks and swells,
The brooklet rings its tinkling bells,
The swarming insects drone and hum,
The partridge beats its throbbing drum.
The squirrel leaps among the boughs,
And chatters in his leafy house.
The oriole flashes by, and, look!
Into the mirror of the brook,
Where the vain bluebird trims his coat,
Two tiny feathers fall and float.

As silently, as tenderly,
The down of peace descends on me.
O, this is peace! I have no need
Of friend to talk, of book to read:
A dear companion here abides;
Close to my thrilling heart He hides;
The holy silence is His voice;
I lie and listen and rejoice.

—John Townsend Trowbridge.

*

AMONG new fancywork we find filet crochet in wool. Baby's crib covers are made of this, in designs of flowers and animals. There are also filet sacques crocheted in princess or Pompadour wool, which has a silk thread running through it. It costs nearly double as much as ordinary wool.

*

RASPBERRY charlotte calls for one pint of raspberries, half a pint of bread crumbs, two eggs, one pint of milk, two ounces of powdered sugar and one ounce of butter. Butter a pie dish, sprinkle with bread crumbs, then put in a layer of raspberies and sprinkle with sugar. Repeat the alternate layers of crumbs, raspberries and sugar until the dish is full, then beat up the eggs and add to the milk, pour over the pudding, dot bits of butter on top, and bake in a moderate oven.

*

MINOR accidents—cuts or contused wounds—are quite frequent on the farm. It should be remembered that such injuries, when trifling in themselves, may become serious, and even fatal, as the result of infection, hence the necessity for strict cleanliness and aseptic treatment. A Wisconsin labor report, referring to the proportion—four or five per cent.—of small factory injuries that proved serious through infection, states that these injuries, during one year, would cost employers about $40,000 for wages and compensation. Aseptic treatment is cheap in first cost, and any family physician will give advice to his patients as to methods and materials.

*

A COMBINATION preserve new to us in muskmelon and red plum. It calls for four pounds of melons, four pounds of red plums, and five pounds of sugar. Halve and stone the plums, and mix with about half the sugar. Peel the melons, remove seeds, and cut the flesh into half-inch dice, and add the remainder of the sugar. Cover the melon seeds with their adhering pulp and the plum stones with water, boil half an hour and then strain, cracking the plum stones and mixing the kernels with the fruit. Let the fruit stand in separate dishes for several hours, then pour the boiled liquid over the melon, cook slowly for 40 minutes, then add the plums, and boil slowly for 30 to 40 minutes longer, or until it will set like a marmalade. Another combination, cooked in the same way, is two pounds of melon, two pounds of red currants, three pounds of sugar, and two lemons, grated rind and juice. The lemon juice is not added until the jam is almost done.

*

A RECENT magazine story told of two elderly spinsters who, unable to take a trip on which they had set their hearts took their needed change by crossing the street—Maria into Selma's house, Selma into Maria's. Thus each one could look across the street at her own house, instead of at her neighbor's; Selma took care of Maria's goldfish, and Maria of Selma's chickens. It sounds rather absurd, and yet how much such a change might mean to a woman condemned to the same monotonous round. Very few could change into another house, like the two contented spinsters, but many could get a certain rest and refreshment by changing their rut, even in trifling ways. We have heard people speak rather contemptuously of the various forms of fancywork, as an amusement for hard-working women. It is true that some of it is quite futile, and some is deficient in beauty, but that is because the worker's industry has not been directed aright. So long as a woman has this interest, her mind will be alert to learn new things, and she will remain receptive. Let us be thankful for any influence that keeps us in touch with others, and delivers us from the possibility of an ossified mind.

Seen in New York Shops.

ONE pretty black velvet hat seen was trimmed with begonia flowers of white Brussels net. These consisted of the usual four round petals, each about four inches across, made by drawing net over a piece of white milliner's wire, and gathering the ends firmly together, so as to make a round petal shirred together at base, where the center of the flower was finished by a disk of yellow stamens. Such flowers are easily made, and are used for dress trimming as well as hats; they take the place of the butterflies that were used for trimming last year.

Fall blouses, which are now being displayed, show a preference for white Japanese wash silk—Habutai. They still show the rolling collar and drooping shoulder. Such waists, in good quality, cost around $3 and up readymade.

Some pretty new underwear is of sheer nainsook piped with flat bands of delft blue. There is no lace or embroidery; the garments have the beauty of fine material and good cut, without extra trimming.

Beach coats of terry cloth are made to slip on over a bathing suit. These are loose, three-quarters length, and belted; the material absorbs the water like a Turkish towel, and protects against sunburn.

English coats for country wear are intended for driving, motoring, golfing and other sports. Many of them are of tweed woven on hand looms—real wool, carefully dyed, and woven just as similar fabrics were made by our great-grandmothers. Short coats of Cumberland tweed cost $18.50; they come in white, bright colors, and also dull heather mixtures; three-quarter lengths, with patch pockets and leather buttons, are $27.50. We wish such handloom cloths could be woven in country districts here, providing an outlet for wool, and home work for the farm family.

Coat dresses of linen after French models look very much like little girls' Gabrielle dresses of about 1872. They hang in straight lines, hardly touching the figure from the shoulder down; the sash or belt is loosely draped around the hips. They combine all the virtues urged by dress reformers, and are very stylish, but very odd in unaccustomed eyes.

New Fall suits are shown in redingote models. There is a plain tight skirt, and the long loose coat of cassock shape. This cassock coat has a high plain collar and deep cuffs of caracul cloth, the suit being made of broadcloth. Colors shown are the very dark brown called tete de negre, midnight blue, Russian green and black.

Separate basques are already offered readymade in satin, black, white and navy blue. They are straight, semi-fitting, and trimmed with fancy buttons, some having a deep waistcoat girdle, collar and vest of moiré.

Shirred ribbon elastic bands finished with a big white satin poppy are meant to hold together sets of lingerie or dozens of towels or napkins. They make an acceptable gift for an engaged girl's "shower."

Little towels and wash cloths of soft crash are offered for baby's use. The towels have an edging of crocheted lace, and the word "Baby" cross-stitched above it in delicate colors. The wash cloths have a narrow crocheted edge and a stork cross-stitched in the corner. These are suitable little gifts for the new baby.

The Rural Patterns.

In ordering patterns always give number and size desired. Price of each pattern 10 cents.

7525, Plain blouse or guimpe. Cut in sizes 34 to 44 bust measure. Size 38 re-

quires two yards of 36 or 44-inch material with one-half yard 36 for peplum. 8302, Ladies' yoke blouse. Cut in sizes 34 to 42 bust measure. Size 38 requires 2⅝ yards of 36-inch material. 7839, House gown or nurse's costume. Cut in sizes 34 to 46 bust measure. Size 38 requires 5¾ yards of 36-inch material with three-eighths yard 27-inch wide for collar and cuffs. 8022, Three-piece skirt. Cut in sizes 22 to 30 waist measure. Size 26

requires 3⅜ yards of 36 or 44-inch material. 7768, Four-gored skirt for misses and small women. Cut in sizes 14, 16 and 18 years. Size 16 requires 3¾ yards of 36-inch material.

8283, Boy's blouse. Cut in sizes four, six and eight years. Size six requires 1⅝ yards of 36-inch material with three-eighths yard 27-inch wide for trimming. 7412. Boy's Russian suit. Cut in sizes two to six years. Size four requires 2½ yards of 36-inch material with three-quarters yard 27 for collar, cuffs and belt. 7164, Men's outing or negligee shirt. Cut in sizes 34 to 46 breast measure. Size 40 requires three yards of 36-inch material. 6599, Boy's baseball suit. Cut in sizes eight to 14 years. Size 12 years requires 4¼ yards of 36-inch material with one-half yards 27 for bands. 7485, boy's blouse. Cut in sizes four to 12 years. Size 10 requires two yards of 36-inch material.

Morning Cooking.

IN the cool of the morning I try to make my desserts and prepare many of my dinner and supper dishes in hot weather, and I find that I can accomplish more at sewing or housework with the knowledge that all these things are ready. If company comes unexpectedly, or callers or business calls take up part of the morning I do not get uneasy, for I know that 40 minutes' quick work in the kitchen will make matters all right and insure dinner on time.

Shortcake made with berries, cherries or ripe peaches is one of my standbys. I make the cake early in the morning and set it in a cool place so the baking powder will lie dormant until needed. We have an early dinner, so I make a quick fire, pop my cake into the oven, bring out the washed berries and in 20 minutes the cake is ready for the table. Rice custard, tapioca custard, fruit custard and other soft puddings are baked at breakfast time and merely warmed over, if I serve them warm. Apple sauce is treated in the same manner and all kinds of stewed fruits. I put the fruit in a crock and set in the oven out of the way. It will cook and keep hot till dinner is served. Rhubarb sauce is excellent in this way.

We like cold roast or boiled meats for dinner in the very hottest weather, so I cook the meat in the early morning. If we want it hot I put it in a big stoneware crock and cover closely. In this way it is hot at dinner time and we can have hot gravy. Stewed chicken is a favorite dish, but for this I keep a low fire and simmer it till noon, as we use the fat old hens for stews. Most of the cooking is done before breakfast, and the oil stove will finish it gradually.

Most people do not like warmed over vegetables, and our folks are among the number, but it isn't necessary to warm them over. I shell my peas and mix up the cream sauce in the morning, so that 20 minutes' cooking will finish them. Beans take longer, so I start them at breakfast and finish at noon. Tomatoes need little cooking, and cabbage we usually serve in the form of slaw. The green corn is picked, but not husked, in the early morning, and, then plunged into boiling water just before needed.

Bread, pies, cookies and all doughnuts are manufactured in the early morning. I know a berry pie is not quite so good made and left to stand, but we mostly use berries alone or in shortcakes. The pies I make and allow to stand are those not injured by a wait of five or six hours. Lemon, apple, peach and grape pie are really better to our tastes when cold than warm on a hot day. When I am forced to eat in town at a restaurant I know the pie was made the day before, so I consider that pies allowed to stand a few hours will not injure anyone.

One can hardly count it cooking to make frozen desserts in the morning, yet most of my recipes involve more or less cooking. When I can have ice I make up a big freezer of ice cream in the early morning and go on my way serenely with little fire either at dinner or supper. Ice cream is an ideal dessert if made at home, and we are very fond of it. It is really the easiest dessert of all, but not having ice always handicaps me.

Then there are baked beans, succotash, brown bread and a dozen and one other things that can be made in the morning before it gets very hot. These served cold or warm for dinner and supper lighten my work and give me more time to rest and enjoy life. The men like the cool dishes better and they are more wholesome. The time was when I thought it shiftless to use these makeshifts but I am bravely over that notion and glad of it. HILDA RICHMOND.

The Canning of Vegetables in the Home.

IT is quite as important for a healthful diet, as well as from an economical point of view, that the farmer's wife have on hand as goodly a supply of canned vegetables for her table during the Winter months as she has preserves, pickles, and jellies. But usually, aside from tomatoes, a wealth of tender young vegetables are annually allowed to ripen or go to waste in garden and field, under the impression that they are difficult to keep. Perhaps some of you, back in your early days of housekeeping, did attempt to can a few jars of beans or corn, and failed, all your precious time and labor in the undertaking resulting in your dumping a disgusting mass in the garbage pail, but that was simply because you did not apply the proper methods, it is just as easy to keep string beans or corn as it is peaches or berries when once you know how.

Of course you all know the secret of successful canning of fruit lies in cleanliness, a careful sterilization of jars and utensils used in the operation, as well as perfect fruit, and the same rule must be applied to the canning of vegetables, except that the latter are a better medium for the growth of bacteria, mold or germs, therefore it is necessary to cook or sterilize a vegetable longer. In order to sterilize a vegetable completely it must be heated to the boiling point and allowed to remain at this temperature for at least five hours, or one hour for three successive days. The latter method has been proved by the Department of Agriculture to be the most satisfactory for the killing of bacteria and its spores or seeds.

For the successful canning of vegetables as well as fruit good jars are indispensable. The glass ones are preferable to those of tin. Jars with wide mouths, and glass tops held in place by a wire spring, are the very best. These can be secured from almost any dealer, the better grades usually retailing at $1 to $1.25 a dozen, and if carefully handled they will last for years. Do not use old rubber rings, always buy new ones each season; a defective rubber has been the cause of many a can of fruit or vegetable spoiling. As a rule the black ones are better than the white ones, they are more firm, therefore less likly to stretch or become porous.

With jars carefully selected, the next step is the choosing and preparation of the vegetables. Do not attempt to can more than one variety at a time. Young vegetables are preferable to those more matured, their flavor is more delicate and the texture tender and crisp. They should be gathered early in the morning and prepared as soon as possible afterward, or after the sun has gone down, then put in cold water or in a cool damp place until morning. All vegetables to be canned should be firm and crisp when first put into the jars.

For sterilizing the vegetables, especially if you intend to do a number of jars at one time, there is no receptacle better, and one that is within the easy reach of every housewife, than the ordinary clothes boiler, either tin, copper, round or oblong, it will not matter so long as it has a close fitting cover. Have a piece of heavy galvanized wire, with rather a small mesh, cut to fit inside this, so the jars will not rest on the bottom. Narrow strips of wood, small stones, or straw is sometimes used for this purpose, but the wire netting is more convenient and sanitary, then too, it can be set away and used the next season.

CANNING STRING BEANS.—String fresh young beans, and break or cut into inch lengths. Add one teaspoonful of salt to each quart, and pack firmly into jars, and cover with cold water. Place on the rubber rings and covers without pressing down the wire spring at the side of the jar. Place the boiler on the range, put in the false bottom, and set in as many jars, taking care that they do not touch each other, as it will hold. Pour in three or four inches of cold water, it is not necessary to have the water reach up to the necks of the jars as was once supposed, it is the steam that will do the sterilizing. Place on the boiler cover, and bring the water to a boil, and keep it at this point for one hour. At the end of this time take off the cover and allow the steam to escape. Lift out each jar separately, and push down the spring at the side as for sealing, and set aside, or return to the boiler for the next days boiling. On the second day raise the spring at the side of the jar, place boiler over the fire and boil for another hour as before. Again remove jars, push down the spring, and allow them to stand in the same manner as the preceding day, and repeat this process the third day. At the end of this time remove the jars, clamp down the tops, and let them stand in the closet for two or three days, then test. This is best accomplished by first releasing the spring, and picking up the jar by the top, if there has been the least bit of fermentation, or the sterilization is not perfect, the top will come off. In this case the jar should be returned to the boiler and resterilized, but it is safer to throw out the contents and refill with fresh vegetable. If, however, the top is secure you may be sure your vegetable is properly sterilized and will keep as long as you wish.

CORN.—Corn should be prepared for canning as soon as possible after the ears have been pulled from their stalks. There is no vegetable that loses its original sweetness and good flavor so quickly as corn after it has been gathered. Choose only the ears with full clean grains, rejecting any defected with black spots or rust. Husk, and with a stiff hand brush remove all the silks, then shave off the grains with a sharp knife, and pack the jars full, adding one teaspoonful of salt to every quart of vegetable, and fill up the jars with cold water, then proceed to sterilize in precisely the same manner as string beans.

ASPARAGUS, PEAS AND LIMA BEANS are put up in the same way as string beans or corn. Succotash is perhaps the most difficult to keep, the two vegetables, corn and lima beans, combined seem to furnish an excellent medium for bacteria development, so the utmost care must be taken in canning it, it is safer to boil the jars containing the mixture two hours each day instead of one hour.

BEETS canned while young and tender are far superior to the matured ones we keep in the cellar during the Winter months, as also are young turnips, carrots and parsnips. These vegetables are first prepared as for the table, cooked until tender, then sliced and packed into jars, filled up with cold water, and sterilized. Cauliflower may be canned in the same manner. Summer squash should first be steamed until tender, then packed into jars and sterilized for one and one-half hours for the three successive days.

TOMATOES.—Tomatoes are easily kept owing to the acid they contain. Peel perfectly ripe but firm tomatoes, cut them into halves, press out the seeds, then divide each piece into smaller ones. Put them in a preserving kettle, and cook slowly for 30 minutes, then transfer to perfectly clean jars and seal. Should you wish to can them whole, choose only the small round ones, put them into a colander or wire frying basket, and plunge them into boiling water, drain, and remove the skins, then pack in wide mouth jars, fill up with cold water and sterilize in the same way as you would for string beans. ROSAMOND LAMPMAN.

Keeping Stove Clean.

THE best way to keep the stove clean is to have the top polished at a foundry or machine shop. This gives a permanent, bright, smooth, surface and is easily cleaned. As it becomes spotted or dull, scour with emery cloth paper wrapped around a block of wood. Then wipe off with damp cloth. It always looks nice and is easily washed. I believe it is worth the trouble. Enamels or paints burn and peel off. MRS. A. F. K.

Three Trouble Savers.

IT frequently chances that one wants a tubed cake pan either larger or smaller than the ones available. Any pan may be made into a tubed pan, by making a cylinder of stiff paper, and placing this in the centre of the pan, let someone hold the paper cylinder in place, and pour the cake batter around it, you will find that this makes a very satisfactory makeshift in time of need.

The kitten struck a playful claw through the invalid's hot-water bottle, and behold, a leak in a very good cloth-lined rubber bag resulted. We had a patch of rubber vulcanized on the orifice, but after one day's use the patch loosened at one corner and the water still oozed out. The girl who thinks of things mended the bag and after it had been well-tested she told the secret. Her father applied flexible collodion to cracked thumbs, and she thought it might apply to rubber tissue. The bottle has been used and used hard for some time since, and still that little patch holds with its unique and impromptu "stickum." Although we stumbled on to this method, we certainly did not "fall down" on it, as the saying goes.

Chewing-gum may be a pernicious product, and its legitimate use much to be deplored, but it has come in very handy in the house. A leaking gas pipe has been plastered over with chewing gum, and the gas been held in proper place until a delinquent plumber could attend to the matter. A small leak in a water pipe was similarly stopped, temporarily. A bit of cloth could be wound around to hold the gum-moulding intact if needs be. In fact many small leaks are mended temporarily with this small and inexpensive medium. ROSE SEELYE-MILLER.

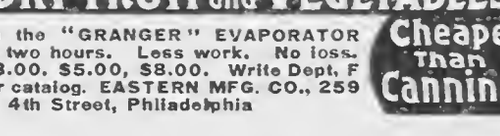
Old-fashioned Apple Dumpling.

Slice apples in a baking dish, getting it heaping full. Then stir up a batter made as follows: One teacupful of buttermilk, or more according to the size of the dish; stir in flour, very, very thick, half teaspoonful soda and one or two tablespoonfuls cream. Cover the apple entirely with this mixture and bake. I like to turn a basin over it a few minutes before serving. Serve just as it is. If batter be too thin it would be likely to run over in oven. E. C. C.

R. N.-Y.—In the Middle West we met this dish under the names of pan dowdy and also apple cobbler.

BEEF GOULASH.—Two pounds of lean beef cut into inch squares. Three large onions, sliced. Two tablespoons of drippings, one cup of chopped cabbage, eight small potatoes, one teaspoon of salt, one teaspoon of paprika, one cup of water and one-half cup of milk. Place the dripping in a kettle. When smoking hot add the meat. When the meat is brown remove from the kettle and put in the onions and cabbage. Then put in the meat. Add the seasonings and the water. Cook very slowly until the meat is getting tender. Then add the potatoes. When they are done add the milk. Boil up once and serve.

The Thick Sheet
"Wear-Ever"
ALUMINUM FRY-PAN
is excellent because it stores up such a large amount of heat that it sears the meat immediately, cooks thoroughly and quickly.
"Wear-Ever" utensils are stamped from thick, hard, sheet aluminum, without joint, seam or solder -- cannot chip or scale --are pure and safe.
Replace utensils that wear out with utensils that "Wear-Ever"
Send for Fry Pan Recipes (free)
WANTED: Men to demonstrate and sell "Wear-Ever" Specialties. Only those who can furnish security will be considered.



The Aluminum Cooking Utensil Co.
Dept. 53, New Kensington, Pa., or
Northern Aluminum Co., Ltd., Toronto, Ont.
Send me, prepaid, sample 1-quart "Wear-Ever" stewpan, for which I enclose 20c in stamps--money to be refunded, if I'm not satisfied.

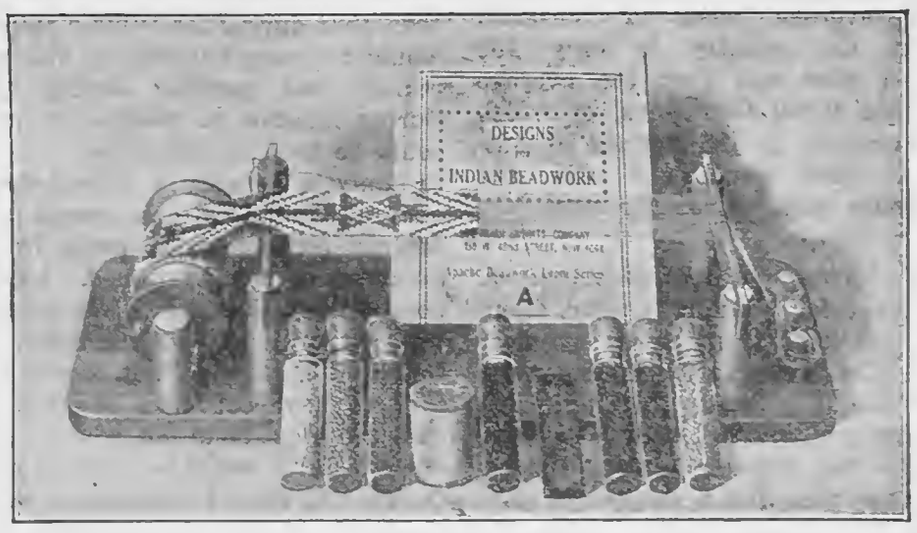
Indian Bead Work



NOTHING is more fascinating or more in vogue at this time than **Indian Bead Work articles.** We have procured an outfit for making these articles, which will be sent, delivery charges prepaid, for

ONE NEW YEARLY SUBSCRIPTION
OR
THREE YEARLY RENEWAL SUBSCRIPTIONS
(One of these may be the renewal of your own subscription for one year.)

This outfit consists of a Patented Loom for making articles, an instruction and design book, a spool of cotton, twelve H. Milward Sons' needles, seven bottles of colored beads—dark blue, green, light blue, black, red, yellow and white—a complete outfit to start the work.

Every woman knows and appreciates the value of these home-made articles.

Live Stock and Dairy

THE BROWN SWISS BREED.

MUCH has been written concerning this well-known breed, and there has been some discussion as to whether it should be rated as a dairy or dual-purpose breed. The Brown Swiss cattle are rated as dual-purpose animals only by Americans. The cows have always been regarded as dairy animals by the Swiss people, and nothing is more distasteful to them than to know that their favorite dairy breed is considered only mediocre as milk producers by American authorities. In all fairness, it should be stated that this rating is given on account of the inability of the Brown Swiss breed to present the form demanded by the American standard in judging dairy cattle.

RECORDS AS A DAIRY BREED.—I am like our editor in that I do not believe the milk-producing capacity of a cow or the egg-laying ability of a hen can be told by an external examination alone. The measure of the spring of rib, size of barrel, width of hip, length of tail, diameter of milk wells or texture and capacity of the udder are important points, but no system of lineal measurements will tell the number of pounds of butterfat a cow will produce in a year. When the Brown Swiss form is compared with that of the commonly accepted dairy breeds, the comparison is so unfavorable that the Brown Swiss is called "dual-purpose," if there be such an animal. However, when this breed is judged by the milk and butterfat production of the individual animals, it becomes a dairy breed. Some years ago, when Mr. F. H. Mason was United States consul in Switzerland, he reported that at Cham, where the Anglo-Swiss Condensed Milk Company was supplied by 6,000 cows, the average nine months yield was 5,315 pounds. This was obtained by feeding only grass and hay.

Before me I have a report by Ira Inman, Secretary Registry of Production for the Brown Swiss breed, in which he gives some of the recent records which were completed the first of June. Of the mature cows, the lowest record is 9,016.3 pounds of milk and 328.51 pounds of butterfat, while the highest record is 14,145.9 pounds of milk and 575.29 pounds of fat. In the two-year-old class, the lowest record is 6,223.8 pounds of milk containing 259.11 pounds of fat while the highest record is 11,312.2 pounds of milk containing 477.10 pounds of fat. Added to these, the fact that old College Bravura 2nd produced over 19,000 pounds of milk in a year has become a matter of history, and unlike so many cows after they have made the world's record, she is a good cow yet. When we consider that the average yield of butterfat throughout the country is only 150 pounds per cow and that the average yield for the 2,800 Guernseys, of which we have records, is 425 pounds of butterfat and 8,500 pounds of milk, the Brown Swiss rank favorably with the other dairy breeds.

BROWN SWISS CHARACTERISTICS.—A dark mouse color shading lighter along the back and head is preferred by most breeders. The conformation is somewhat blocky, while the head and neck are rather large and covered with long hair. This makes the animals appear coarse, and taken together with a sleepy eye, they present a temperament which is usually called "lymphatic." The limbs are particularly straight. The cows range between 1,400 and 1,500 pounds in weight usually and the one great point of dairy excellence, as judged by the score-card, is the udder. It is usually well hung, ample, and decorated with well-placed, good-sized teats, one at each corner. The Brown Swiss is a dairy breed. However, the number of purebred individuals in this country is very limited and will necessarily remain so as the government has issued a quarantine against their importation on account of the prevalence of the foot-and-mouth disease in Switzerland. I. J. MATHEWS.

Ingham Co., Michigan.

CYNICUS: "I once knew a fellow who gave a girl an engagement ring of opals." Sillicus: "Gracious! Wasn't it unlucky?" Cynicus: "You bet it was! She married him."—Judge.

A BUNCH OF DAIRY QUESTIONS.

WOULD it be possible to go into the market and purchase 25 or 30 cows (grades) that, with a ration of corn silage and Alfalfa hay, would yield a gross income for a year of $60, with good care and pasture in Summer? 2. About what would these cows cost per head? 3. How many pigs could be grown and fattened from the skim-milk of 30 cows, and what would it be necessary to add in order to balance the ration for the pigs? 4. Would it be just as profitable to feed the skim-milk back to the cows as it is to feed it to the pigs? 5. What is the proportion of corn silage and Alfalfa hay to feed to a cow in milk when no grain ration accompanies it? 6. If a cow is fed all she will eat of a ration of corn silage and Alfalfa, we know the flow of milk is not so great as it would be where there is grain or something similar added, but will the difference in the amount of milk or butterfat pay for the additional grain ration? 7. Are the present day milking machines entirely practical where one has to depend upon help to operate and care for same, with a personal supervision of only once a week, but with telephone connection? A. F. G.

Pennsylvania.

1. It would be quite possible to go into a dairy district and purchase the cows as suggested that would yield a gross income of dairy products amounting to $60 per year. It might be good judgment to add a small amount of grain to the silage and Alfalfa ration, but if uniformly good individuals were selected they ought to meet this condition without much effort.

2. Grade cows of good age, tuberculin-tested, would cost from $90 to $135 each, the price varying with the individuals, somewhat with the breed selected, and also depending upon their stage of lactation. It is not uncommon to pay $150 for a grade cow of known usefulness.

3. Assuming that the 30 cows would yield an average of 10 quarts of milk per day, which would indeed be high, it would mean the yielding of approximately 250 quarts or let us say, 500 pounds of skim-milk a day. This amount of skim-milk could be used to advantage in the feeding of a herd of 25 brood sows and their progeny. It is assumed, however, that during the Winter months there would be some animals on the place fattening, and possibly during the early Spring months, in which case more milk could be used to advantage. A safe rule to apply in general is to feed five pounds of milk for each one pound of grain, slightly increasing the grain in case the animals are being fattened. In this proportion they should be given all that they will eat or drink with relish. In addition to the skim-milk it would be necessary to have ear corn, digester tankage and red dog flour or wheat middlings. Some Alfalfa could be used to advantage during the Winter months, in which case it would require only ear corn, and this hay to balance the ration for the brood sows, provided some digester tankage was added to the ration as farrowing time approached.

4. It would not be profitable, in fact the system is not practiced by successful dairymen of feeding back to the cows the skim-milk. It can be used to advantage in feeding calves, but is not a safe nor an economical practice to use in the herd.

5. If the animals are fed only corn silage and Alfalfa hay they should be permitted to consume all that they will eat with relish of both products.

6. I have oftentimes claimed that there are a great many dairy cows that might yield 50 pounds of milk per day at a loss when they would give 40 pounds of milk at a profit. This difference results from the cost of the extra amount of feed, and oftentimes is not keenly appreciated by the dairymen. For instance, if a cow is fed eight pounds of grain per day, and gives 40 pounds of milk, and the ration is increased to 12 pounds of grain per day, and the milk flow increased by only five or six pounds, it is plain to be seen that the added amount of grain is not properly utilized. It is true that cows will not give as much milk on Alfalfa and silage, but it is very probable that the cost per unit would be less, and the net profit greater. Whether the difference in the amount of milk or butterfat produced would pay would depend upon a number of factors. In the first place silage and Alfalfa are both bulky feeds, and the animal would be able to digest and assimilate a larger amount of food nutrients than she would consume of these bulky feeds in case there was any question about their condition or palatability. In other words she would consume a maintenance ration, but whether or not she would consume a maximum amount would be the question. Undoubtedly she would last much longer if she was fed in this way than if fed concentrated feeds, and less difficulty would be experienced when being mated. It would be good judgment to try under one's conditions the addition of a small amount of grain, and determine by such means the extent of the profit.

7. I think it must be admitted that the milking machine is as yet in the experimental stage. Instances can be cited where the machines have been used to a distinct advantage, and with entire satisfaction to the owner, and again they have been used tentatively and discarded and condemned by the owner. Machinists usually do not apply for positions on dairy farms, and it must be admitted that it requires considerable skill to operate the milking machine, and keep it in good working order and repair. It would depend largely on the kind of help that your correspondent is employing. This argument has been met, however, with the statement that in large dairies they have no more trouble in operating the milking machines than exists in their endeavor to get responsible milkers. F. C. MINKLER.

BROWN SWISS BULL, CARL 3577.

PUREBREDS FOR CHEESE DAIRYMEN.

"I AM $10,000 ahead by breeding purebreds for the past seven years," declares James Haynes of Ashtabula County, Ohio. "Purebreds for the man who receives cheese factory and creamery prices for his milk are the best profit producers. I am not looking for my income from market milk, but my stock put my returns on the right side of the ledger. That is why I want to give the dairyman who only gets an ordinary price, the hint to get into good stock. Get the good, and breed better. When I first started in the purebred business, my father-in-law drove over to inspect my 'fool' buy, and he gave me the laugh. I bought just one cow, and here is where I made a mistake. I would have been a year ahead had I bought more than one. My first calf was a bull calf. Well, in spite of what my father-in-law said about the black and white stock, and my brother's assurance that in two years the best would not demand more than $10 above that of the grade, I rolled up my sleeves and went into the game. I sold the scrubs at public sale, and invested in good stock. Then whenever I happened on a couple of neighbors visiting they looked cheap, seemed to have side-tracked their conversation, and I know they had been talking 'fools not dead yet.' I am just an ordinary farmer, and many farmers, not all, can do as well as I. First select your breed, and stick to it, whether it be Holstein, Guernsey, Jersey or Ayrshire. Feel satisfied with your breed, read about your breed and advertise your stock, and your breed. The breeds are all good, and the competition among the breeds is what is keeping interest and prices alive.

"Another proposition is to get the best bull you can. That is where I first made a failure, in the belief that one registered bull is as good as another. Here is where I was wrong. I did some breeding to ordinary registered animals when I was in the primary class in registered stock. Now I have learned through experience and reading that that is the wrong system. Breed to a bull which is better than your best cow, and follow that practice. If I had to breed one of my good cows to an inferior bull I would hesitate a long time, for the live stock end of my dairy is the profit producing end, while my neighbors are vealing calves for $10 or $12, with close, if any profit over cheese factory milk prices. I have a liking to older bulls, for, in my experience, they produce more heifer calves. Every time I have changed bulls, I found that I had more bull calves when a young animal is introduced.

"I would advise in selecting a bull to get one with a history behind him. Get one whose ancestry not only has transmitting ability, milk production, but butter fat as well, and breed for better stock. Buy the best bull you can and if you are short the cash, try to co-operate with some of the breeders within a dozen miles of your home and buy a bull that is right. That is what I am trying to encourage some of my breeder friends to do.

"There are some men whom I would not advise to engage in high-bred stock, and those men are poor feeders. They are men who are gruff in their homes, and who are unkind in their families and herd. They are poor feeders, and the purebred animal will not stand the grief that a dung-hill is able to withstand. When I look back and see that I have paid my original $1,700 investment, and nearly $2,500 besides, and have now conservatively figuring $6,000 in stock, while the income from the dairy products have gone further in maintaining the family and improving the farm than a greater number of scrubs, I feel that I have accumulated over $1,400 each year for the past seven years in the form of live stock pretty easily, and I find that the man who keeps pure-bred stock is on the right trail."

Mr. Haynes is only milking a dozen cows, four of which are in the A. R. O. class, and he intends putting the remainder of his herd under test for advanced registry the coming Winter.

W. J.

Mare With Bruise.

I have a 12-year-old mare, weight about 1,150 pounds. A large soft, swelling or tumor has appeared on her chest, between the shoulder blades. It is swelling farther down between fore legs. It has a slight fever. In no possible manner could collar have caused the swelling, as it is too far below. Her health otherwise is in good condition. What can be done for it?

Pennsylvania. H. D.

The swelling no doubt comes from bruising on the manger or floor, or from striking by the neck yoke. Tie her up short in a stall so that she cannot lie down, then bathe the swelling with hot water three times a day. When heat and pain subside the swollen lump remaining may be painted with tincture of iodine each other day. If a serious abscess (cyst) forms, it may have to be opened by a veterinarian. A. S. A.

Depraved Appetite.

I HAVE a cow that freshened October 15, and after taking the calf from her in December, she formed the habit of eating droppings in the henhouse, and even picks them up on the yard when turned out to water. I have to keep her in the stall all day. She is rather thin, but eats well. I also have a young sow which farrowed February 6, since which time she has also taken up the same habit. Please tell me what I can do for them? D. J. D.

Virginia.

Feed plenty of wholesome feed to cow and sow and they will not waste time eating hen manure. Make them take abundant exercise out of doors every day. Add roots or silage to the rations, and make bran one of the chief feeds of the cow. Bran fed generously soon stops depraved appetite in cattle. Possibly the reason is that bran contains a lot of phosphorus. Phosphate of lime, or ground bone, may also be given when cows pick up bones, earth and other foreign matters. Indigestion is present in such cases as you describe. Add 10 per cent. of digester tankage to the rations of the sow.

A. S. A.

IS THE BERKSHIRE DISQUALIFIED?

WE purchased a Berkshire pig from a breeder, a show hog. He has one front leg white, a white spot behind his leg, and a white spot on his shoulder. Wouldn't this disqualify him in any show ring? G. B.
Greenwich, N. Y.

Irregular white markings on a Berkshire do not disqualify an animal from registration nor from competing in the show ring. Color is largely a matter of individual preference, some breeders preferring Berkshires with six white points, as the score card calls for, namely a spot in the forehead, four white feet, and white switch. Others do not object to white markings appearing on the flank, or even on the body. Occasionally one finds what is known among breeders and show-yard exhibitors as a "swirl," that is, a patch of white hairs seemingly growing or pointing in the wrong direction. With some judges this might disqualify from consideration, but in my judgment it would be foolish to discard a perfectly good animal as far as conformation and quality is concerned, simply because his color markings were not just as desired. By way of comparison a great many Guernsey breeders object seriously to what is known as a dark nose. Their official score card gives one point, on a basis of 100 to the color of the nose, and yet it is often recorded that certain judges would not under any circumstances consider an animal whose nose happened to be other than flesh color. The color of the milk is far more important than the color of the nose, and while it is important to adhere to a definite and carefully established type, in my judgment it is a mistake to consider such points so seriously.

In case of the Berkshire referred to if he has the characteristic Berkshire conformation about the head and neck, evidences development of back, ham and rib that is desired from a butcher's standpoint, if he shows thrift and an abundance of vigor and vitality, his color would be no objection. Of course, there are instances where a great deal of white would evidence a lack of pure breeding, and might indicate a dash of blood from some white-haired breed, and of course, such instances should immediately disqualify an animal if there is an abundance of evidence that the animal is not of pure breeding or properly registered. It is not uncommon to find among Berkshires hair of a sandy color in spots over the body .in fact a great many of the very best Berkshires are splashed with white or sandy color.

Value of the sire depends upon what he is able to do or leave behind him, and not what he presents in the way of color and conformation, and while it is always good judgment to stay if possible within the bounds of the score card established by the various breeders' associations for the different breeds, utility should be the dominating factor, and trivial fads or fancies should not be catered to. To me the development of those parts of the animal's carcass that add to his utility value is far more important than trifling variations in color. I do not think that any reasonable judge would fail to consider the animal referred to if he was properly fitted, and of suitable conformation, and evidenced quality to the extent that is desired in the modern pig. F. C. M.

HANDLING A KICKIMG COW.

I NOTE that H. C. H. is having trouble with a kicking heifer (page 938). I have yet to make the acquaintance of the heifer or cow which cannot be restrained or cured by the following methods. Put the animal with kicking proclivities in a good stanchion. In the wall on the other side of the passage in front of the cows put a good strong staple and ring, about 3½ or four feet from the floor, and directly in front of the cow to be dealt with. If the subject has horns tie a rope (*strong one*) around them and make a loop in it close up in front of her head. If she has no horns use a good stout halter and make the loop close to her nose. Take a pair of light tackle blocks, and hook one in your ring in the wall and the other in your halter or rope. Pull good and taut, and fasten with a slip hitch where you can readily loosen your rope (don't use ratchet or self-locking tackles). Sit down and milk. Your confirmed kicker will in all probability "start something" and land in a heap, on the floor. Loosen up, get her up, and tighten up and start in again. A very few tumbles with her neck fairly well stretched will usually teach even a cow that it is best to keep all four feet on the stable floor and stand quiet. If your kicker begins to yield to treatment it may work well to bring your rope back and tie it so that it will pass over your head and in reach of your right hand. Now don't make your hitch quite so taut and if your patient begins to fight take hold and pull firmly and quickly. Such a reminder of past experiences will sometimes work wonders.

Always remember that in handling cows, and especially kickers, you need to be quick to act, slow to wrath, very slow, and never use the "rawhide" except in extreme cases, and then it should be in the hands of a man of strong will but good judgment. We have handled some bad cases in the above manner, and when I tell you that we make a business of buying young heifers, keeping them until they freshen and are well broken and then sell them off to make room for more, you will understand that I have had a chance to give the method described a good "tryout." P. C. D.
New York.

I SEE that H. C. H. asks about a kicking heifer. I send my remedy; it has been successful a number of times. Take a strap with a buckle or a rope with a loop in it, put it around the body just in front of the udder, and cinch it tight. Then when she kicks, it will throw her. Have it in a bow-knot or a buckle so it can be easily loosened. She cannot get up with it tight. After a few trials she will give it up. I have had some cases where I would have to lay the rope or strap across the back for a while, or put it on loose until they got over the habit. A. N. G.
Tennessee.

ON page 938 an inquirer asks how to cure a kicking heifer. Fasten her head up so she cannot move it much. Tie a rope to her left hind foot, then make a hitch around the right foot, so that it may be pulled back a little further than a good milking position, then fasten to a ring in the floor or the partition back of the stall. If this is done right she will not be able to move, and I have seen two very bad kickers cured by this trick.
New York. N. W. B.

OUR Ayrshire would look at the milker, and if her large black eyes discovered that he needed a change, she would land the milk pail against the rear wall, and that bucket never recovered; the milker too was lucky if he escaped a thump. She was young and a large milker, and we hardly wished to almost give her away. We tried this plan: First she was treated kindly and given feed or salt; was stanchioned in the old wood stanchion and we put a blanket on her. Ours is duck, about 9x6 feet. We milk carefully, and if she kicks, use a strap and use it on her leg she kicks with. Our strap is a part of our old halter; don't spare the rod and spoil the child, put it on. That one was completely cured, and this year we have cured another promising heifer and the two operations, making good cows from those, is worth more than $100 to us. D. C. K.

A MILKING FAMILY.—Prof G. G. White of the Connecticut Agricultural College reports a Holstein family: De Kol Hubbard Pietertje now has a great grand-daughter. It will be remembered that De Kol Hubbard Pietertje made the State record by producing in one year 23,175 pounds milk and 1,038 pounds butter. Her daughter, De Kol Hubbard Pietertje 2nd produced in March this year 2,038 pounds milk, in April 1,835 pounds, in May 1,959 pounds and in June 1,767 pounds. The grand-daughter, Minnie Hubbard De Kol, freshened at 28 months of age and in less than a week after freshening milked up to 38 pounds in a day. The great grand-daughter is now only a few days old.

SOUR MILK AND CALVES.—On page 915, you say: "The Department of Agriculture reports experiments in feeding sour milk to calves and that in no case did it cause digestive disturbance." While we have successfully raised calves on sour milk, we have also lost them by bloat. We once had a calf that would invariably drink so fast as to cause it to choke. One morning in drinking, it choked worse than ever, and frothing from the mouth. Someone advised giving it soda, saying that was highly recommended. In my desperation I administered a dose, and had I taken a hammer and knocked that calf down, it could not have dropped any quicker—dying immediately at my feet. Moral, don't give soda with sour milk.
F. M. W.

DAIRY CATTLE

Holstein-Friesian Bull Calves For Sale—Write for special offer. THE GATES HOMESTEAD FARM, Chittenango, N. Y.

Holstein Calves—3 to 5 weeks old, 15-16ths pure, well marked, $20 each, crated for shipment anywhere. Edgewood Farm, Whitewater, Wis.

READY FOR SERVICE—PRICES, $75.00 to $150.00 Registered Holstein and Jersey Bulls. Splendid individuals with great backing. Best blood in the land. Also younger bull calves. Write for list. HOMEWOOD FARMS, RYE, N. Y.

HOLSTEINS—Registered bull calves, $35.00 each. High grade Holstein heifer and bull calves 1-week old, $15.00 each. October shipment express paid in lots of 5. 100 High Grade Holstein Cows; 60 Yearlings and 2-year olds; 60 head of Registered Holsteins. Reference, 1st National Bank, Tully, N. Y. REAGAN BROS., -:- TULLY, N. Y.

DAIRY CATTLE

FOR PRODUCTION—BREED UP, NOT DOWN—Registered Jersey bull calves, only, from producing dams and highest type sires. R. F. SHANNON, 603 Renshaw Bldg., Piltsburgh, Pa.

For Sale—ONE TWO-YEAR-OLD —ONE YEARLING PUREBRED Jersey Bulls Registered. Solid color. Price reasonable. DOE BROTHERS, - Bradford, Vermont

DAIRY BRED SHORT HORN

BULL CALVES FOR SALE. Fine ones, priced right. JOHN R. WILLIAMS -:- OVID, N. Y.

YOUNG REGISTERED HOLSTEIN BULL 127791, now ready for sale. Well bred, handsome individual, even black and white. $135. We have two others more fashionably bred and higher priced. MOHEGAN FARM, Hudson Valley Headquarters for Purebred Stock. CHAS. H. BAKER, Owner, Peekskill, New York

REGISTERED HOLSTEIN YEARLING BULLS Sired by Colonel Korndyke De Kol, one of the best sons of Pontiac Korndyke. Also 4 grandsons of the King of the Butter Kings, from choice heavy-milking dams, at popular prices. Write me what you want Donald F. McLennan, Syracuse, New York

Registered Holstein Yearling Bull whose 12 nearest dams have official records that average over 500 lbs. milk and over 23 lbs. butter in 7 days, whose sire, Admiral Walker Gelsche, has 34 officially tested daughters, the only bull in New England that has a daughter with a record over 30 lbs. G. F. GREGORY, Dummerston Farms, Dummerston, Vermont

Buy a Bull on Easy Terms

Long Time and 4 Per Cent Interest

Holstein bull calves, sired by a SON OF KING OF THE PONTIACS, whose dam has a record of 29.57 lbs. butter in 7 days and 113.96 lbs. in 30 days, and out of A. R. O. DAMS. WRITE AT ONCE for breeding, prices, and particulars regarding our terms. JUSTAMERE FARM, Middletown Springs, Vt.

East River Grade Holstein Cows For Sale

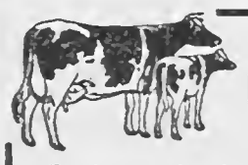
100 cows served to calve in August, September and October, all served to registered bulls. STRICTLY DAIRY TYPE AND GUARANTEED. 60 yearling heifers. 40 two-year old heifers all sired by pure blooded bulls from high producing dams. 10 extra well-bred registered bulls, PONTIAC BREEDING, from A. R. O. DAMS. If you are looking for extra good dairy cows, visit the EAST RIVER HOLSTEINS. Special price for the next 30 days. WE TUBERCULIN TEST. JOHN B. WEBSTER, Dept. Y, Cortland, N. Y. Bell Phone 14, F.5.

HIGH GRADE **HOLSTEINS**

100 cows due to freshen in Sept. and Oct. 100 fresh cows and springers.

PRICE, $75 to $100.00 EACH

All large, well bred, nicely marked and heavy milkers. 100 2-year-old heifers due to freshen this Fall, and all in calf by registered bulls. You can pay more but you can't buy better. F. P. SAUNDERS & SON, Cortland, N. Y. Office, 50 Clinton Ave.



Purebred Registered **HOLSTEIN CATTLE**

In the production of milk and butter the larger the cow the larger the profit, other things being equal. This principle has been established through the investigations of government experts and is generally recognized.

When a cow's milking days are over, size is still an important factor. The big Holstein-Friesian, weighing anywhere from 1,000 to 1,800 pounds with her clean white fat well distributed through her muscular system, proves a most profitable dairy beef animal.

Day after Day, Year after Year, **PRODUCTION COUNTS**

It is not what a cow can produce in 7, 14, or 30 days, even in a year that determines her value to the farmer. It is what she can do in a lifetime.

Brown Swiss Cows rank high in average production and are regular and persistent breeders and producers. Year in, year out, they make good records and raise good calves without any coaxing or pampering. If interested, we will send you an illustrated booklet.

The Brown Swiss Cattle Association

IRA INMAN, Secretary BELOIT, WISCONSIN

FEEDING PROBLEMS.

Feeding Value of Wheat.

CAN we afford to feed wheat to growing shotes or feeding hogs? At current prices, wheat 71; corn 80 cents a bushel and hominy meal $28 per ton, it seems wheat could be fed cheaper than corn. I have an idea a ration of half wheat and half hominy meal, wheat either being ground or soaked, would make a good ration. C. V. E.
Clayton, Ind.

There is very little difference between the feeding value of whole wheat and whole corn for use with swine. The wheat if soaked or ground and fed alone in the form of a slop is very apt to cause disorders of the digestive system, it being rather doughy in its nature, and at the price quoted, namely wheat at 71 and corn at 80, I would suggest equal parts of corn and wheat to which 10 per cent. of digester tankage has been added. The hominy at $28 per ton could be substituted safely for the corn, yet I would prefer feeding the ground wheat and tankage in the form of a slop, and let them have the corn on the cob. I do not think that it pays to grind corn for pigs unless they are very small, and even at this age they should not be given large amounts of soaked or shelled corn. Your suggestion of a ration of equal parts of ground wheat and hominy would do very well in case you fed in addition some digester tankage. The comparative analysis of wheat, corn and hominy feed is given below:

	Water.	Ash.	Crude Protein.	Carbohydrates. Fiber.	Carbohydrates. N-Free extract.	Fat.
Cornmeal....	15.0	1.4	9.2	1.9	68.7	3.8
Hominy feed	9.6	2.7	10.5	4.9	64.3	8.0
Wheat.....	10.5	1.8	11.9	1.8	71.9	2.1

You will note that there is not a great deal of difference between the wheat and the corn, it being a question of palatability. The digester tankage will increase the palatability. Furthermore, by means of cost comparison, wheat at 71 cents per bushel would be at the rate of $23.66 per ton, while corn at 80 cents per bushel, figuring 60 pounds to the bushel, would be at the rate of $26.66 per ton. F. C. M.

Question About Feeding Wheat.

"DO you consider wheat of equal value with corn for feeding hogs?"

Experimental work indicates that wheat and corn are about equal pound for pound as a hog feed. Both corn and wheat have about the same composition. The wheat is considered a little better ration for growing animals, corn on the other hand being preferred as a fattening feeding stuff. Since wheat and corn have about the same composition, being high in carbohydrates and fat, or energy building nutrients, and low in protein, or muscle-building nutrients, they should both be supplemented with some other feed such as tankage, linseed oil meal, skim-milk and the like. In other words, when wheat is added to the ration it should be considered a substitute for corn rather than a supplement to corn.

"Is there danger in feeding a single wheat ration on account of digestive troubles?"

Data on the above subjects is rather conflicting. The results of some experiments say that such is the case, while that of other experiments do not record this difficulty. The Missouri station last Winter fed straight wheat to shotes for 120 days without any bad results along this line.

"In feeding wheat to hogs, should it be crushed, ground fine or fed whole, and should it be fed dry or soaked, and if soaked, will it injure it to sour it or should it be fed sweet? The cost of grinding is about five cents a bushel in this State."

Among other things, Henry in his Feeds and Feeding, has the following to say upon this question:

Rommel, summarizing nine trials at five stations where whole or ground grains—peas, wheat, rye, oats and barley—were fed, either dry or soaked, to fattening pigs, found that it required approximately 473 pounds of whole grain or 415 pounds of ground grain to produce 100 pounds of gain—a saving of 12 per cent. by grinding.

The above does not apply to corn, but to the small grains like wheat. The Nebraska Station has unpublished data which indicates that better results may be expected with soaked ground wheat than with whole wheat which has been soaked. They found that even when the whole wheat was soaked, much of it passed through the hogs. In their experiment the increased gains made by grinding more than paid for their cost of grinding, which was estimated at four cents per bushel. While I know of no data on the subject it is usually considered that crushed or coarsely ground wheat is to be preferred to that which has been finely ground, since it does not form such a sticky mass in the hog's mouth. There is no data to show that any advantage is to be had by soaking the wheat after grinding. Most men in practice, however, prefer to feed it wet rather than dry, since there is not so much danger of its being wasted. If not allowed to become too sour, souring will perhaps give as good results as sweet feed. However, there is no advantage in feeding it sour. It should always be fed one way or the other, i.e., sweet feed should not be fed once and sour feed another, since this kind of feeding is apt to cause indigestion.

"Would you expect better gains by feeding wheat and corn mixed than when either is fed alone?"

Experimental work indicates that a mixture of corn and wheat is more efficient than when either of these feeds are fed alone. I should advise, however, that the ration also include a small amount of some feed such as tankage or linseed oil meal.

"When corn is worth 75 cents and wheat 65, in what proportion would you feed it to pigs weighing from 75 to 150 pounds, and to hogs in the fattening period, 150 to 250 pounds?"

A good ration for the lighter weight shote would be corn five parts, wheat five parts, tankage one part by weight. For the heavier shotes the amount of wheat and corn might be increased until the corn and wheat would make up from 12 to 16 parts of the ration. The younger the shotes the larger the amount of tankage required.

"With corn at 65 cents and wheat at 70, and hogs at seven cents, will it not pay better to feed wheat to hogs than it will to sell it?"

With feeds at the above prices it would pay better to sell the wheat than to feed it, since the ration of corn and tankage would be more economical than a ration of corn, wheat and tankage, or wheat and tankage.

"What do you think of wheat as a ration for brood sows?"

There is little of any data available showing the value of wheat when fed to brood sows. There is somewhat a prevailing opinion in sections where wheat is used to a large extent for this purpose that the wheat will cause barrenness in brood sows. As stated above, however, there is no definite data to show that this is the case. Wheat in limited amounts is to be recommended and the price of wheat as compared with corn makes the feeding of wheat economical.

"What is the best way to feed wheat, on a feeding floor, or in troughs?"

Since it is recommended that wheat be fed ground and wet, it would be best, of course, to feed it in troughs. The Missouri Experiment Station has some unpublished data along these lines and is planning to conduct further tests and hopes to have data available for distribution along this line in the near future.

Feeding Young Bull.

I AM raising a purebred Holstein bull. He is now 11 months old. I do not need him for service until June, when he will be 16 months old. I am told by a number of farmers that if I grain him too heavily to grow him I will spoil him for breeding purposes. Let me know your opinion on this. I am feeding corn and oats (ground) equal parts in weight. They claim they have known dairies to go farrow by using such a bull. C. W. M.
Rossburg, N. Y.

The bull calf designed for breeding purposes should be handled and fed in such a manner that it is certain he reaches his full natural development. Ground oats and corn, equal parts, makes a good grain mixture, and should be fed liberally. While there is no advantage in getting the bull calf fat while young, there is no special harm done if he appears a little smooth and beefy at this age. An underfed animal remains undersized, and while his progeny will not necessarily be smaller on account of a characteristic caused in this way, it is impossible to know whether his undersize has been caused by inheritance or under feeding, and he is always looked upon unfavorably. F. C. MINKLER.

LIVE STOCK NOTES.

THE present dairy conditions in this section are very good. Pastures are in good condition, with the prospect that they will continue so for some time. The hay crop will be from one-third to one-quarter better than last year. The treasurer of the North Pitcher Creamery informs me that the price patrons have received for their milk thus far in 1914 is a trifle better than for the same period last year. While most herds kept in this neighborhood are grade Jerseys and Holstein, some of our farmers are working into registered stock. Most of our thrifty farmers are interested in improving their herds by using purebred bulls. "Is there any profit in the dairy business at present prices?" That depends on who the man is. In support of this conclusion I will relate a bit of information at hand and leave you to draw your own conclusions. Within a short distance of where I write there lives a dairyman, who in addition to his dairy keeps several hundred hens. A few years ago his farm was covered with a heavy mortgage, but by hard work and the exercise of good judgment he has not only lifted the mortgage, built a large barn and house with modern improvements, besides has accumulated a substantial bank account, and after accomplishing this he invested in an automobile, and while he is still on his job and sees to it that nothing goes to waste, he occasionally has a day off and takes a spin about country. I am told of another man in a nearby town, whose worldly goods consisted of a hundred-acre farm, stocked with a herd of 10 cows, the income from which he depended upon to support his family of seven; recently he sold his 10 cows for $750 and invested the money in an automobile. Granting this to be true; we may reasonably expect that at least one of three things will happen; either he will wear out his automobile going about the country trying to make himself and others believe that dairying does not pay, or dispose of his farm and retire to some city and join the vast army of kickers; or else the transaction will teach him a lesson, which in after years may be well worth the price of an automobile.
Chenango Co., N. Y. H. D. F.

Value of Hay Caps.

HOARD'S Dairyman gives the following testimony for hay crops:

"The excessive rains during nearly the whole of June have produced very serious loss to the first cutting of Alfalfa in Wisconsin. Where hay caps were not used, in many instances there has resulted an almost total loss of the cutting, and even when a portion was saved the damage to its feeding value may be fairly estimated to exceed 66⅔ per cent. where no hay caps were used. On the Hoard's Dairyman Farm, for example, we have had nearly 40 acres standing in the cock under caps from two to three weeks. The result is that all of the bottom of the cocks on a considerable portion had to be thrown aside and drawn to the manure heap. The balance comes out in very fair feeding condition. There has also been serious injury through the smothering of the roots under the cocks as it was impossible to pull them over upon fresh ground often enough to prevent this injury. Without the hay-caps we would have lost about the whole of the first cutting. As it is, we have saved and put into the mow in the last few days, in fair condition the entire crop with a loss not to exceed 10 to 15 per cent. When we consider the high feeding value of Alfalfa it is amazing to us to see how many farmers there are who attempt to grow it without making any provision for safe curing with hay-caps.

AN exceedingly fat man approached the Pullman window and asked for a lower berth. He was told that there were none left. "Gimme an upper, then." "Pardon me," said the ticket seller, as he took a glance at the Falstaffian proportions of the man, "but you'll never be able to get into an upper." The fat person smiled grimly. "I won't have to," quoth he. "When the man who has the lower berth has a look at me he'll be glad to change."—Chicago Live Stock World.

THE EGG-LAYING CONTEST.

WHITE LEGHORNS continue to make all the high scores. Seven pens of the White Leghorns laid 50 eggs or more during the week. The highest number reached by any of the 14 other breeds represented in the contest, was 46, laid by Albert T. Lenzen's White Plymouth Rocks.

The great event at Storrs this week was the three-day meeting of the Connecticut Poultry Association, and presence of, and three lectures delivered by, Mr. Tom Barron; also Mr. Barron's demonstration at the contest plant of his ability to pick out the birds that were good or poor layers. It is not in my power to give a synopsis of these "talks" of Mr. Barron, but they were taken down by a stenographer, and will be published in full later. It was Mr. Barron's first attempt to address an audience from a public platform, but the simple, straightforward, honest personality of the man, "captured" the audience at once; and he could not appear after that without being greeted with a round of hearty applause. He told how he got his first Wyandottes, and how he had bred them since, and all the talk there has been in this country about his cross breeding, was dissipated into thin air, and there was no need of his hearty denial, to get that thought entirely out of the minds of his hearers. The attendance at the meetings was about double that of any previous meeting, and poultry notabilities from far and near were present.

The report for this, the thirty-ninth week, shows Mr. Barron's pen of White Leghorns leading the week's record with a score of 58; Glenview Poultry Farm taking second place, with a score of 56. Marwood Poultry Farm, from Butler, Pa., is third, with a record of 54. Francis F. Lincoln's pen tied with A. B. Hall's pen for fourth place, with scores of 51 each. P. G. Platt's pen laid 50, as did A. B. Hall's pen. The week's record follows:

GEO. A. COSGROVE.

Sick Turkeys.

IN April, 1913, we started turkey raising. We had five turkeys, but all except one hen died last Summer, the one being saved by the use of one-tenth grain calomel tablets. This turkey hen started to lay April 3 of this year, and has laid up to June 26, about 55 or 60 eggs, all of which were infertile, as we could not find a purebred tom. June 20 the turkey ate a great deal of wheat, which caused her to become ill, as it is now fermenting in her crop. We have been doctoring her with calomel, but have been giving her three-grain quinine capsules, as we thought that too much calomel would kill the turkey. Would you advise us as how to treat this turkey?

Jefferson Barracks, Mo. F. M. H.

I would not depend too much upon drugs in the case of sick turkeys, or humans either; there are comparatively few whose action we fully understand, and they should be used as adjunets to hygienic and other care rather than as the sole dependence in sickness. The calomel, given in moderate dosage and for short periods of time, was very likely beneficial to this turkey, and about one grain of quinine per day would be of some value as a bitter tonic. Their value and the beneficial results of their use are likely to be very much overestimated, however, especially by those whose knowledge of the action of drugs is limited. It is not at all unlikely that your other turkeys died of that great scourge of turkeydom, blackhead, and that this one survived either by reason of a milder infection or of greater constitutional vigor. This disease has rendered turkey raising a most precarious occupation, not only in your State, but in most others of the union. No real preventive or cure has yet been found though much study is being given to it. I would suggest a full dose of castor oil—about a tablespoonful—to this sick turkey and after its action a limited diet in which soured skim-milk forms an important part. This latter should also be fed to the poults from the start in the hope that it will exert the same beneficial action that it shows when given to chicks subject to infectious bacterial diseases.

M. B. D.

Weak-legged Cockerel.

I HAVE a young rooster about 14 weeks old, weighs three pounds 14 ounces. He seems to be so weak in his legs he can hardly stand. Can it be he is growing beyond his strength? Could you tell me what it is and what to do for him? I feed crushed oats, cornmeal, oatmeal and beef scraps, also whole corn.

New Jersey. M. S.

Common causes of leg weakness in fowls at any age are heavy feeding with too little exercise and rheumatism from confinement to damp quarters. I would give this cockerel free range upon dry ground and feed him sufficiently sparingly to induce active exercise upon his part. If he does not recover under this care, he should be discarded and not used in a breeding pen.

M. B. D.

Black Yolks.

WHY do eggs from healthy hens have black yolks? Eggs are gathered three times a day. For two weeks I fed rye and oats, equal parts and bran, all they can eat; they have free range. No cockerels run with them. I have one-half acre of rape close to henhouse; chickens eat lots of it. F. J. Y.

Ohio.

The only explanation of black yolks in eggs that I can offer is the presence of blood clots, which usually are found in the white of the egg but may occur either upon or within the yolk. Blood clots are caused by over congestion of the egg-making organs, with occasional rupture of a small blood vessel and consequent formation of a clot which is included within the egg as it forms. Heavy feeding, especially upon meat food, and the use of condiments is believed to contribute to it. The remedy is more green food and less food of a stimulating nature, plenty of exercise and no attempts to unduly force egg production. It may be that you have several hens that are especially subject to this trouble and if you can detect them they should be removed from the flock. If your hens are all affected, I can offer no explanation of the phenomenen.

M. B. D.

Sour Milk and White Diarrhœa.

I AM pleased to read, on page 936, that C. B. H. has been able to raise so high a percentage of chicks infected with white diarrhœa, after using my method of squirting a pen dropper full of sour milk (lactic acid) down the throat as soon as dry, or described in my article on page 790. C. B. H.'s experience is the same as other poultrymen who have tried it.

Here at Broad Brook Farm all chicks are on range and growing fast and strong, some of the pullets are laying. Of 5,013 chicks put in the brooders, total loss to date is 1,181, chicks or 23.1 per cent. All this goes to prove the great value of this method of filling the chicks' crops with sour skimmed milk (lactic acid) as soon as they are dry enough to take from the incubator. It also proves that sour skimmed milk given at this time will overcome the disease and make it possible to raise a high percentage of chicks hatched from eggs laid by infected hens. One dose at this time has more value as a preventive and cure than all the sour skimmed milk fed as soon as the chicks are able to drink it themselves.

New York. EDWARD S. PARSONS.

Droopy Chicks.

CHICKENS four weeks old stand around droopy, will not eat. They act like that a day or two and die. They have been having chick feed, scratch feed, wheat, whole corn, mash made dry of mixed feed and sour milk. Can you suggest a remedy? W. H. C.

New York.

Chicks that reach the age of three to four weeks and then droop and die are usually suffering from intestinal disease due to infection and ordinarily show more or less diarrhœa. There is little or nothing to be done for them after they show symptoms of disease, and the proper course is to prevent infection by hatching only from vigorous, healthy stock; keep the chicks upon clean, uninfected, ground; ground that has not been used before by sick chicks; clean and disinfect all brooders before using; and finally, feed an abundance of sour skim-milk from the start. This latter food seems to have a markedly beneficial influence in preventing the development of diarrhœal diseases. In a flock showing these symptoms, all affected chicks should be promptly removed and their careasses buried; the quarters of the flock should be thoroughly cleaned, new, fresh, litter used, eating and drinking utensils scalded with boiling water; sour milk added to their diet. If the greater part of a flock are affected, it may be well to discontinue the use of hatching eggs from the same stock, some diarrhœal diseases are transmitted from hens to chicks. M. B. D.

Don't Let Lice Get Hold of Your Flock

—to breed, cause endless irritation and all manner of skin diseases and sore spots. Take *quick* steps to get rid of lice.

Dr. Hess INSTANT LOUSE KILLER

Kills Lice. Kills them quickly—surely. Sprinkle and rub it thoroughly into the feathers. Put it in the dust bath, sprinkle it in the laying nests, roosts and cracks. Instant Louse Killer also kills lice on farm stock, bugs on cucumber, squash and melon vines, cabbage worms, slugs on rose bushes, etc. In sifting-top cans. 1 lb. 25c; 3 lbs. 60c. Except in Canada and the far West. If not at your dealer's, write us.

Department "M"

The Rural New-Yorker
333 West 30th St., New York City

PUBLISHER'S DESK

I SHIPPED four cases of eggs and four coops of broilers to F. Ehrenkranz, 565 Orange Street, Newark, N. J., for which he agreed to pay 30 cents per pound for broilers and top New York price for eggs. This was three weeks ago, and at that time broilers were 28 cents. By the time he received them they had dropped to 25 cents. He received them the 7th of July and wrote me they were too small and had no feathers, and wanted to know what to do with them. He dated his letter the 8th; it was postmarked in Newark on the 10th and delivered out here on the 13th. I wired him at once to ship them to Hance Brothers, New York. He stated in his letter that the eggs were O. K. Saturday, July 18, he sent me a check and letter stating a lot of the broilers were dead and Hance Bros. refused them, and that he got $12 for them. He gave me 28 cents for two cases of eggs and 23½ cents for the other two cases, saying they were very poor. It is very evident to me that the man is trying to cheat me. I am just getting started here and I feel the loss. The goods were all of my own production and I know they were first-class. R. W. H.

New York.

During the past Winter we have had considerable complaint from our subscribers about Mr. Ehrenkranz of the Orange Butter & Egg Co. When we took the matters up with him he disputed each and every item, and it was only by the most persistent dunning we were able to get some of the accounts adjusted. Others are still open. He made various offers for settlement some time in the future, which were not kept. There is little encouragement in this record that future shippers to this party can look for satisfactory settlements if payment is secured at all.

From time to time I have noticed articles referring to a Dr. Ulman's society for suppressing dishonesty and frauds. As I subscribed for your paper since the article appeared first, I must have missed the editorial, but have gathered from the little articles that have been published enough to convince me that I should become a member. Will you explain what is necessary to become such? I take no paper or magazine that prints liquor, patent medicine or what I believe to be fraudulent advertisements. All publishers should be compelled to stand back of their advertisers, and the subscribers are the ones to compel such an act. You are right; where are the women? A large per cent. of the women's magazines of today are full of patent medicine advertisements. There is going to be some hair-pulling before long, and a chance to give that "editor" who allowed one to be swindled, something he won't forget in a minute. N. S.

Maine.

This friend already qualifies as a charter member of the Anti-Fake Club. All that is necessary for anyone to become a member is to send in name and address, and signify intention to report to the club objectionable or deceptive advertising, and the papers in which it appears. The plan will be to first protest to the publisher; and if he persists to refuse to receive the paper. The above correspondent is correct. The subscribers of such papers are the sufferers, and they should compel the publisher to respect their interests. Now that they have an opportunity, we believe they will do it.

Three women have asked to see the next woman's number; we pass ours on anyway, so please may I have three samples of the Woman's Magazine? At least one wants to see it with a view to subscribing. E. S. K.

We shall be pleased to send all the sample copies any of our friends want for themselves, their neighbors and friends anywhere. They may be sent in a bundle to the old subscriber or separately direct to the persons for whom they are intended, if the names and addresses are sent us. We propose to make this woman's number the best magazine in this country for country women. We just want to learn direct from these women what they want, and they shall have it without regard to the work or cost. In other words, we propose to make it equal to the other features of the paper.

Last September, my father bought of the Wauchula Development Co., Wauchula, Fla., 20 acres of land, sending them $20 for the first payment, the price being $40 per acre, one dollar per acre to be paid per month until paid for. A few days later the president of the company wrote us that they were just opening up a new tract of land (the finest in Florida), and why not change our holdings to it. My father then sent $20 more for 20 additional acres of land—10 acres for myself and 10 for my mother, all the land to be in a body if practical to do so. They wrote us that they had selected an ideal tract of combination land suitable for both truck and oranges. In November my father went to Florida, (we were living at Culpeper, Va.,) to inspect the land and to locate permanently, as we had sold our holdings in Virginia. My father arrived in Wauchula about 10 a. m., was taken out to Vandolah (which is eight miles west of Wauchula) to inspect the property allotted to him. He did not like the looks of it, as there were about five acres of water on it, (in several ponds) but their agent, Mr. Vandolah, assured him that "it was fine truck land and that truck land was more valuable than orange land."

My father was rushed back to Wauchula in an auto and up into their office. He was there presented with a card to sign; a card of acceptance for the land, which he signed upon the assurance of Mr. Vandolah that it was fine land. My father stayed for several days around Wauchula, and asked the farmers about the land around Vandolah, and they all said it was no good, being what is called "flat woods pine." He also walked out to Vandolah to inspect it more closely, and he decided he did not want it, so he did not pay any more money out for it. I then wrote the company in December that my father had inspected the land and found it unsatisfactory and asked that they return our money per their guarantee of July 21, 1913. The terms provided that any time within a year we have the right to demand our money back, together with six per cent. interest, if we were not thoroughly satisfied with the investment.

This is the dry season in Florida and I have been told by the natives that this land is covered three and four feet deep with water in the Summer. Mother and I have tried to get our money ($40) back but they refused on the ground that father signed a card of acceptance for it. He did sign the card for his 20 acres but not for ours. They also claim that not having paid up we have also forfeited our rights. They were willing to give us credit for what we had paid if we would take other land, but not to give money back. Now I wish you would see if we could get any of our money back from them—$80 is what we have paid them. The people who are buyers of this land are mostly poor people from all over the country. The company advertises very extensively, but not in THE R. N.-Y. They make much of their bankers' guarantee. R. F. H.

Florida.

We let this young man tell his story for the benefit of people who go to Florida or other places to buy lands promoted by companies and agents. As he says it is poor people who take up such propositions. They have no money and no information to go to law to recover their money. It would cost them more to get it back than the face of it. The promoters know this, and the investors are helpless. No man should buy land anywhere until after he has inspected it, and spent time enough in the neighborhood to become familiar with the condition of the land and the character of the neighborhood. No man should ever sign a contract of purchase while under the influence of one of these land promoters. Spend several days or weeks in the vicinity, interview the natives and the business men, then if you are satisfied, go back to the agent and make your purchase; but you will usually find that you can buy better land from others for less money, and in 99 cases out of a hundred you will keep your money in your pocket and go home satisfied with your prudence and your providence.

Your work of securing, when possible, payment of delinquent accounts for your subscribers and fearlessly exposing fakes is a matter which cannot be passed without special commendation. Surely it is "worth while."

Will you, sometime when you can spare the space, kindly set forth, briefly, in your paper, the purposes and aims of the Anti-Fake Club, what constitutes membership, etc? Wishing you every success, I remain, W. K.

Wisconsin.

The purpose of the Anti-Fake Club is simply to discourage fake and fraudulent advertising; and to protect one another from their illusive schemes and deceptive advertisements. The idea is simply that the members report any deceptive or misleading advertisements that they find in papers or in circulars through the mail. They will protest to publishers who print such advertisements in their papers, and if any publisher persists in carying the objectionable advertisements, then the members of the club would all refuse to receive the paper into their homes.

"WHAT a polished talker Jobson is." "Isn't he? I suppose that's the reason he slips up on so many of his arguments."—Boston Evening Transcript.

Abscess.

WHAT is the matter with my horse? He is a gelding, nine years old, and is troubled with a swelling on the point and side of his right shoulder. It does not seem to bother him while working, but if he rests a few days it gets larger, and finally comes to a head and bursts. Even after it bursts a hard lump remains. It has done this three times within the last six months. The man I got him of used a very poorly fitting collar. Just before it bursts it seems to affect his muscles for several inches each way. Makes him drag his right foot in walking. W. B.

Greenacres, Wash.

Clip off the hair and then open the abscess freely. Evacuate pus or serum, inject a little tincture of iodine, and then pack the cavity once daily with oakum saturated in a mixture of equal parts of turpentine and raw linseed oil.

A. S. A.

Indigestion.

MY driving mare, seven years old has always been a g and roadster, a very free driver and never tires. This Spring she had little pimples over her body in several places. Our doctor said he thought she had been stung with bees some time and it would last in her system for years. He told me to feed her a teaspoonful of sulphur each day for six days and wash her with disinfected water. When driven she is all right till she gets warm, then she becomes nervous and drives badly. I have changed different parts of the harness and used her very easily with no result. I am going to breed her, but I do not want to turn her into pasture. T. H.

New York.

Clip the mare and wash the affected parts twice a week with a 1-100 solution of coal tar disinfectant. Rub in sulphur while skin is damp. The dose of sulphur would be a tablespoonful once daily, with a like amount of salt; but we should prefer to give her half an ounce of granular hyposulphite of soda night and morning until her skin is in good condition. Do not feed corn or grass. Feed a light ration of whole oats, wheat bran and good hay. Work or exercise her every day and let her occupy a box stall when in the stable. Groom her twice a day. Bees had nothing to do with the trouble. She would not be liable to lose her colt if fed as you suggest. If she switches tie a strand of tail hair to her breeching strap on each side of hind quarters. A. S. A.

Hoosier Extension CLOSED and OPEN

Fill Your Silo the Modern Way

Don't cover your silo with the old style roof and have it only three-fourths full after the ensilage has settled. Use instead a HOOSIER OPENING ROOF. A roof that you can open up and will add about six feet extension to your silo. After the ensilage has settled, close, and you will have a perfect roof. The kind of silo cover you have been looking for. It is not only right in theory, but guaranteed to be practical in results. Write for catalog and prices.

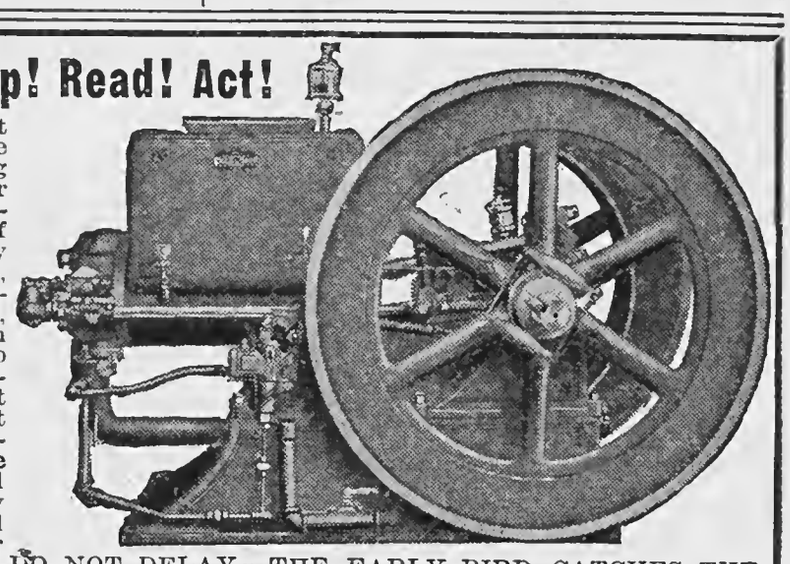
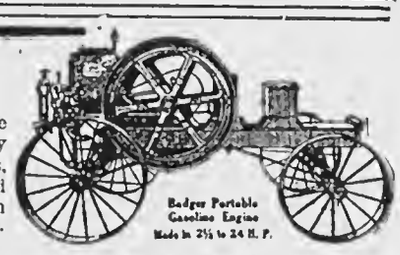
Mr. FARMER: Stop! Read! Act!



Every day you go without an EXCELSIOR gasoline engine you are losing money. Don't take our word for it. Order an engine subject to proof; if you don't find it a money maker, don't keep it. But, if you find it's the best engine you ever saw or used, keep it, pay a part cash after you decide to keep it, and the balance on installments or all cash—just as you like. YOU don't pay a single cent in advance. If you tell us the size of your Farm, and when you will be ready for an engine, there will be something special for you, but above all things, DO NOT DELAY—THE EARLY BIRD CATCHES THE WORM. WRITE TODAY and we will send you some interesting information.

R. CONSOLIDATED GASOLINE ENGINE CO., 202 Fulton St., NEW YORK CITY

For Threshing and Ensilage Cutting



The "Badger" gasoline engine is the best power plant for the big jobs, like threshing and ensilage cutting. Reliability, plenty of power, steadiness and readiness, required for these big jobs, typify the "Badger." Made of the best materials; speed and parts made adjustable; the engine develops more speed than rated at less cost of fuel. Runs by gas, gasoline or kerosene. Consumes no fuel which is not turned into power.

Badger GASOLINE ENGINES

The "Badger" is always ready to run—Winter or Summer—at an instant's notice. Every part guaranteed for five years unconditionally.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending Aug. 7, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914.	1913.
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.01 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.61 and $1.51 for B and C. Hotels and restaurants using two to three cans per day are paying five to 5¼ cents per quart, single quart prices from bakeries and grocery stores, six to seven cents; delivered milk, nine to 10 cents.

BUTTER.

During the week there has been an advance of one-half cent and a decline of one cent on the top grades of butter. Receipts of these grades are not excessive, but business very dull. City-made butter is in good demand; packing stock scarce and one to two cents higher, some sales being made at 21 cents.

Creamery, extra, lb	28	@	29
Good to Choice	23	@	27
Lower Grades	20	@	22
State Dairy, best	27	@	28
Common to Good	18	@	24
Factory	18	@	21
Packing Stock	18	@	21

Elgin, Ill., butter market 28 cents.
Philadelphia, western creamery, 30 cents.

CHEESE.

Market is very firm and one-fourth cent higher on most grades. Imports of special cheese are practically at a standstill, and prices quoted rather nominal, with probability of a substantial increase at next report.

Whole Milk, fresh, specials	15¼	@	15⅜
Average fancy	14¾	@	15
Primo	14	@	14⅛
Under grades	10½	@	13⅛
Daisies	15	@	15¾
Skims, specials	11¼	@	12
Good to choice	10	@	11
Poor to fair	5	@	9⅛

Stilton	46	@	48
Parmesan	25	@	28

EGGS.

The best new-laid are two to three cents higher, but this refers to only a small proportion of receipts. The demand is slow. Receipts from the West are showing irregular quality, close candling being needed to meet the needs of even fairly good trade. There are frequently complaints of strange flavors in eggs, which can be traced to excessive use of condimental foods. The writer has tasted eggs strongly flavored with fenugreek, an ingredient of many foods and "condition powders." Any strong or aromatic flavor is quite sure to make trouble with the eggs. Beef scrap, oil meal, etc., should be looked after carefully. Bad beef scrap is an especially pernicious flavoring for eggs.

Western fresh, white	23	@	26
Lower grades	18	@	20
Storage, best	25	@	26
Lower grades	19	@	24

FRESH FRUITS.

Receipts of ordinary apples are heavy and prices low; some scarcely bringing charges. Unless apples are very scarce there is more profit in giving such culls to the pigs. A few hand-picked Astrachan have been good enough to bring $3 per barrel. Receipts of pears are much larger. Clapp's Favorite from nearby has sold at $3 to $5 per barrel. Many make the mistake of leaving this pear on the tree too long, in which case it rots at the core. Peaches are lower, arrivals being very large. Practically nothing is selling above $2 per crate, and many going at $1.25 to $1.50. Baskets 30 to 75 cents, according to quality. Small fruits mainly low. Muskmelons very plentiful and low.

Apples—New, bu	25	@	1 25
Cherries, 8lb. bkt	10	@	45
Pears, Le Conte, bbl	2 00	@	4 00

HAY AND STRAW.

Some new hay is arriving, selling from $19 to $22. A special caution is needed to make sure that the new hay is out of the sweat before pressing, otherwise it is sure to reach market in bad condition. Old hay is running generally $1.50 to $2 above last week's prices. Old rye straw is $1 higher.

GRAIN.

The market is in very unsettled condition, owing to the European trouble. Great quantities of wheat are being held at seaboard points because of the tie-up of merchant ships, liable to seizure on the sea as prizes of war. Some risks are being taken now, and doubtless other ships will follow if these reach port safely. There seem to be other than speculative reasons for the advance in corn, crop reports indicating considerable damage, possibly a loss of 200,000,000 bushels from the expected yield of 2,700,000,000 bushels.

BUFFALO MARKETS.

THE arrival of green corn is the feature of the produce market. It is of better quality than usual to begin with, and retails at 20 cents a dozen cars. Muskmelons are at five to 15 cents each and of very good quality. Watermelons rather scarce and retailing at 50 cents each for large sizes. Wholesale prices are 15 to 40 cents for watermelons and $1.50 to $2 a crate for muskmelons. Cabbage is low again, especially with the promise of a good crop; beets, eight to 12 cents a dozen bunches; celery, scarce, at 10 to 35 cents a dozen; cucumbers, 20 to 40 cents a dozen, or two for five cents retail; lettuce, 25 to 40 cents a dozen or two medium heads five cents; pease, 75 cents to $1 a bag or 10 cents a two-quart measure; tomatoes, 25 to 40 cents a basket; onions, $1 to $1.25 a bushel, or 15 cents a two-quart measure retail; Summer squash two for five cents retail; eggplant, 15 to 20 cents each, retail. Small fruits are rather plenty and low priced. Currants, red, white and black, 20 to 35 cents a basket wholesale; cherries, six to 10 cents a quart; raspberries, red, 13 cents; black, 11 cents; purple, 10 cents wholesale; blueberries, 14 cents retail. Plums are scarce temporarily, five to 10 cents a quart, sour to sweet. Peaches are of prime quality at $2 to $2.35 wholesale for fine Georgia Elbertas. Bartlett pears retail 10 cents a quart. The home crop promises good. Apples are in great variety. Southern new are $1 per hamper for green and $1.50 for red. There are a few new sweet potatoes, retailing at 60 cents a peck. New white potatoes are rather scarce at $1 a bushel retail. It will be some time before there are many of them for sale by farmers. The growing crop is backward as almost never before, on account of late planting and lack of rain. Poultry is scarce; 15 to 17 cents for live turkey; 16 to 18 cents for fowl; broilers, 20 to 24 cents; dressed, 21 to 22 cents for turkey, 17 to 19 cents for fowl, 24 to 28 cents per pound wholesale. J. W. C.

Subscribers' Exchange

FRUIT, TRUCK, POULTRY FARM—Will sell all or any portion of 36 acres; good buildings, excellent location; immediate possession; no agents. HOMER TWEED, Quakertown, Pa.

FOR SALE—The Mattituck White Leghorn Farm. A new plant, fully stocked and equipped. Will net annually 25 per cent. of purchase price—$8,000. ARTHUR H. PENNY, Mattituck, N. Y.

HOME FARM—Two hundred and twenty-three acres, for sale; with or without stock; extra good place; price reasonable; part cash; or would take active partner. H. C. W., care Rural New-Yorker.

A WOMAN owning a well-established (50 acre) poultry farm (in Connecticut) desires to exchange for a two-family house in or near New York, or will take a partner with small capital. M. E. M., Danbury, Conn., R. D. 18.

VALUABLE FRUIT and grazing land to be sold in Virginia on Sept. 8th, 1914; 475 acres well watered, well located, near railroad, school, churches, modern dwelling and out buildings; no land better for peaches and apples. Owner leaving to practice in town. For particulars address owner, DR. W. C. MOOMAW, Leesville, Campbell Co., Va.

ON POCOMOKE SOUND, Eastern Shore of Maryland, mild, healthy climate, 500 acres fertile soil, beautiful home and buildings; salt water front; oysters, fish, crabs, clams and game plentiful. Will sell at a bargain, or would lease to a party that would buy the crops, stock and farming machinery. Address OWNER, Box 23, R. F. D. No. 2, Marion Station, Somerset Co., Maryland.

A METHODICAL, practical, scientific and successful general farm and dairy manager covering years of extensive and varied experience in exacting operations will be open for engagement Sept. 1. Eminent credentials will be furnished and nothing short of a first-class, responsible and remunerative position will be considered. If desirous, might consider cash proposition of lease of entire property. Address T. J. A., care Rural New-Yorker.

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

WANTED—A housekeeper for small family. A. H. PENNY, Mattituck, N. Y.

JEWISH YOUNG MAN would rent few acres for poultry and board with family; particulars. F. D., R. N.-Y.

WANTED—Position by practical poultryman as manager or poultryman on commercial egg farm. A. J. LUTESINGER, Auburn, N. Y.

AMERICAN—Single, first-class carpenter and painter; also experienced gardener, wants position on gentleman's place or institution. E. C. care R. N.-Y.

SITUATION WANTED—Position, sober married man, either farm work or teaming; capable carrying on farm; no children; references. Box 169 B, Lee, Mass.

REFINER, sober young man (28) wants position on truck or poultry farm; has agricultural experience; wishes good home; state salary. Box 23, 245 East 57th St., N. Y.

WANTED—Position as general farmer or dairyman; would take farm on shares; life experience; best reference; married, Swiss-German, one child. X Z, care R. N.-Y.

POSITION WANTED—On farm, by married man, 40; family; life experience; capable of taking any position or taking charge; best of reference. W. A. MAYOR, Jermyn, Pa. R. 1.

POSITION WANTED—As superintendent or foreman on large farm or estate; lifetime experience in all branches; can handle any proposition; best of references; American; married, one child. Address L. R. F., Rural New-Yorker.

POULTRYMAN—Single, honest, industrious, wishes to take charge of small plant on private place; over 2 years' experience. Open after Sept. 1; references furnished. HERMAN COHEN, R. D. 27, Box 21, Round Hill, Greenwich, Ct.

WANTED POSITION—As repair man on farm or estate, understands steam, gasoline engines, tractor plows, concrete work; can also fill position as herdsman, buttermaker; capable of taking charge; married; small family. Address SOBER, care Rural New Yorker.

POSITION WANTED—By experienced single man; understands creamery work, testing, production, sanitary milk, care and feeding cattle, general farming; first-class buttermaker; college training; practical and sensible; references. Address DAIRYMAN, care Rural New-Yorker.

POSITION WANTED—As manager for farm or estate; would take good dairy farm on shares, thoroughly understand farm crops, up-to-date machinery, steam and gasoline engines, tractor plows, concrete work; New York State preferred; strictly sober, reliable, married American; small family; good refereuces. Address Euergetic, Care R. New-Yorker.

ALFALFA HAY—F. P. ERKENBECK, Fayetteville, N. Y.

EARLY RICHMOND CHERRIES canned on the farm in No. 2 sanitary cans; $1.25 per doz.; syrnped with pits. SENECA FRUIT FARM, Waterloo, N. Y.

FOR SALE—For want of use, cow-pea harvester, cuts, threshes, cleans, in one operation, horse driven; price, $70. W. LERCH, Supt., Scobeyville, N. J., via Eatontown.

SOUR CHERRIES in No. 2 cans, syruped with pits, $1.25 per doz.; Clapp's favorite and Bartlett pears in No. 2½ cans, with syrup $1.50 per dozen. SENECA FRUIT FARM, Waterloo, N. Y.

FIG PRESERVES—Home made; a new delicacy for most people; made from choice fruit right from the tree; few people have ever tasted a fig as it ought to be; write for prices and sample to MRS. M. A. PARKER, Rickerly, near Danphin way, Mobile, Ala.

TO LET OR ON SHARES—112-acre farm in Greene County, N. Y. H. M., c. Rural New Yorker.

FOR SALE—Fruit and poultry farm; 15 acres; annual income $3,000 to $5,000. Price, $6,000. My age, the reason. Z. T. TURNER, Elcroy, Ill.

FOR SALE—Farm in Warren Co., N. J., 150 acres of fine land with good buildings; one mile from station; price $3,800, part cash. J. VASBINDER, Blairstown, N. J.

10 ACRES on main road; house, barn, orchard; fine location, $400 cash; opportunity to co-operate in poultry business at extra profits. ENOCH HAIGHT, Long Eddy, N. Y.

FARM—Rent or sale, easy terms; 220 acres, situated 42 miles from New York City on the main line Lehigh Valley and Central Railroad New Jersey. J. C. W. RANKIN, Crauford, N. J.

DO YOU NEED FARM HELP

We have many able-bodied young men both with and without farming experience, who wish to work on farms. If you need a good, steady, sober man, write for an order blank. Ours is a philanthropic organization and we make no charge to employer or employee. Our object is the encouragement of farming among Jews. THE JEWISH AGRICULTURAL SOCIETY, 176 Second Avenue, New York City.

The FARMERS' BUREAU an agency exclusively for agricultural help. Only first class farm help and positions solicited. References investigated. Scientific advice on farm problems. Dept. R, 150 Nassau St., N. Y. Phone, 5565 Beekman

Farmers! SEE HERE! 50% sacrifice to close estate. 195 acres best valley land in New Jersey; all under cultivation; two miles from two railroad stations; on macadam road. Cost deceased owner $136 an acre; $68 an acre will buy it, with buildings. E. E. SLOCUM, 141 Broadway, New York

HUMOROUS

MR. LOBSTOCK: "Has yo' any faith in banks, sah?" Mr. Bentover: "Yassah! I has plenty o' faith in 'em, but I's done got muh money buried in de ground."—Judge.

POSTMAN: "Bad luck, Mr. Doolan! Here's a black-edged letter for you." Mr. Doolan: "It's me poor brother Pat, dead. Oi'd know his handwritin' anywhere!"—Melbourne Australasian.

OWNER OF BULLDOG: "Excuse me, sir. but would you like to buy a dawg?" "No, thanks very much. He looks as though he would bite." "'E won't bite yer if you buy 'im, Guv'ner."—Punch.

BLOBBS: "Which do you prefer—life in the country or in the city?" Dobbs: "I'm not sure. It depends on whether I am in a mood to be attacked by a cow or a motor-car."—London Farm and Home.

WILLIE (rushing into old Dr. Sawbone's consulting room): Say, doctor, mother says please yer to come quick. Baby's swallowed the latchkey an' we can't get in the house.—Melbourne Leader.

CUSTOMER (irascibly): "Your hair restorer has made my hair come out more than ever." Barber: "Ah, you must have put too much on, sir! Made the hair come right out, instead of only half way."—Melbourne Leader.

THE YOUNG BRIDE: "I didn't accept Jim the first time he proposed." Miss Ryval, (slightly envious): "I know you didn't dear." The Young Bride: "How do you know?" Miss Ryval: "You weren't there."—London Sketch.

"OH, George, before you get your razor I must tell you that I—I borrowed it yesterday." "What, again!" "Y-yes. I had to do some ripping. But it's just as good as ever. You'll never notice the difference. I sharpened it on the stove pipe."—Cleveland Plain Dealer.

UNCLE EZRA: How did your automobile accident happen?" Uncle Eben: "Well. you see, there's one thing you keep your eye on, and another one you keep your foot on. and another one you keep your hand on, and I guess I got my anatomy in the wrong places."—Judge.

"How much is radium worth an ounce?" asked the man with an arithmetical mind. "That," replies the praetical person, "is an idle question. After you get through imagining an ounce of radium you haven't imagination enough left to imagine the price."—Washington Star.

"POOH!" said the one scornfully. "The idea of your being afraid of a poor old house dog! Why, he eats out of my hand!" "I don't doubt it," replied the other, dubiously, "but what I am afraid of is that he may take a notion to eat out of my leg."—London Farm and Home.

"AH!" sighed the boarder who was given to rhapsodies, as they sat down to the Christmas dinner, "if we could only have one of those turkeys that we used to raise on the farm when I was a boy!" "Oh, well," said the pessimistic boarder, "perhaps it is one. You never can tell."—Puck.

"MR. Smith, won't you please talk to me?" "Why, certainly, my little girl. But what do you want me to say?" "Won't you please talk like you did when you were talking to yourself in the library when the dog jumped at you? Mine's so straight, and mamma said the way you talked made her hair curl."—Baltimore American.

THE OHIO STATE FAIR
COLUMBUS

WINNING a prize at Ohio State Fair is a sure sign that a real live citizen is getting home from third base.

When the honors of the show ring are given to an animal, its owner is in the King Row of good breeding.

When the Blue Ribbon of merit is laid upon the finished products of skill, toil and soil, somebody has gotten upstairs in his business.

The Ohio State Fair shows result of mixing brain with sweat.

Finding four-leaf clovers and horseshoes may be omens of good luck, but winning State Fair premiums is a surer road to profit.

A State Fair prize winner votes before noon on election day.

The State Fair Booster will give a dollar to any good cause.

The State Fair Builder would rather see Santa Claus than a king.

A good State Fair man will return the dollar he borrows from his wife. Applause.

Ohio State Fair visitors are seldom pale or emaciated. They are red blooded and at quick-step.

He, who in his own good way helps to build a great Exposition, is laying brick and stone in the walls of a greater state and a greater nation.

The Ohio State Fair is the trophy field on which can be laid the results of teaching, preaching, experiment and experience.

How many progressive folks dare enter the arena of peaceful battle and by their success or failure be measured by what they do?

The water's fine. Dare you take the plunge?

A. P. SANDLES, President.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. LXXIII, No. 4269. NEW YORK, AUGUST 22, 1914. WEEKLY $1.00 PER YEAR.

ROOT DISEASES OR SOIL "SICKNESS" OF WHEAT.

Low Yields Not Always Due to Poor Soil.

FUNGUS TROUBLES.—The wheat yield and the price of wheat in this country, at least in the corn belt, have been so low for many years that its production is conducted on a very narrow margin of profit. In addition to this, the yield is so variable as to introduce much uncertainty into the crop, since an actual deficit often results in a poor year. Various attempts have been made to locate the trouble and devise remedies; but while some improved practices have given results that are really remarkable, it has not been possible up to the present time to put wheat growing in the corn belt in the clear money-making position which so important a crop should occupy. Recently, however, some studies have been made of crop-limiting factors as applied to wheat which give promise of enabling an increase in yield at a small expense to the farmer. These studies have to do with some inconspicuous blight diseases caused by a number of seed and soil-borne fungi. This discussion will be limited to a consideration of this phase of wheat production; not, however, with the idea of minimizing the importance of other and longer studied factors.

INVESTIGATING THE FUNGI.—The work on these diseases has, directly or indirectly, been carried on in a large number of places. In this country the Ohio Experiment Station, the Bureau of Plant Industry of the U. S. Department of Agriculture, and the North Dakota Experiment Station have been most active in investigating them. The investigations at the last named station have probably included more field observations and trials than any of the others. This work (reported in North Dakota Bulletin 107) coupled with laboratory work done there and at other places, has shown that at least six species of fungi aside from the well-known smuts and rusts operate to produce disease in wheat, or at least regularly accompany it. Most of these fungi are harder to fight than are the smut fungi, too, not only because they and their work are not so easily detected, but also because they are able to live, grow, and fruit on dead matter and can, therefore, maintain themselves for some time in the soil without their host plants. They occur and do damage throughout the range of wheat culture, but they are most abundant and their ravages are most severe where wheat is the main crop and is therefore often raised year after year on the same soil, as in the Northwest and in Canada.

SYMPTOMS.—The symptoms of attack by these fungi vary considerably, but are usually sufficiently definite to indicate the disease. Infected seedlings are usually stunted, the leaves may turn yellow or brown so that they are described as having "tip-burn," "sunscald," etc., and many of them may die. The root system is smaller than in normal plants and many of the roots are in various stages of destruction by one or more of the fungi. Often they are so thoroughly destroyed as to give the impression that they have been eaten by insects. The infected roots may be black or pinkish. Normal roots vary from pure white to greenish. The stooling of such plants is seriously checked. Many times from one to a few stalks mark the limit of a plant in this matter. The straw is often soft and breaks over easily. It often has deformations at the joints which are usually taken for insect attacks. The heads do not fill properly. In many cases only the lower half of the head is filled, the upper half being empty or filled with shrivelled light grain. The quality of the grain itself is poor. Instead of being dark in color and hard and horny in texture it is light and soft—distinctly inferior in milling quality. Many grains are black at the stem end and others are pinkish all over. Many others are shrivelled or curiously puffed up or blistered and light in weight. Such is a brief statement of the chief symptoms visible to the unaided eye. With laboratory facilities it is possible without much difficulty to examine the spores which occur on the outside of the grains and from the kind and relative numbers present come to some conclusion as to disease conditions.

SOURCES OF INFECTION.—The chief sources

THE FIRST LESSON IN MILKING. FIG. 437.

of infection for the crop are two, the seed and the soil, although doubtless infection does occur otherwise. The work at the Ohio Station, for instance, shows that the scab organism will infect plants at blossoming time and cause the typical disease. The amount of damage done as a result of this type of inoculation is relatively small as compared with that from earlier infection, however. The diseases are usually carried to new regions by the seed, partly by means of spores clinging to the surface of the grains and partly by means of infected seeds which contain the living threads of the fungus within. Once established in the soil, they can maintain themselves on the organic matter there at least for a year or so. If wheat be planted on this same soil year after year, they are constantly present to attack it; and if, as is usually the case, the seed wheat used each time is infected, the soil receives a fresh inoculation each year. In a few years such soil becomes so "sick" that the production of a large crop of first-class wheat on it is out of the question. That such unproductive soil is not exhausted of its plant food materials has been proved by Prof. Bolley by sterilizing a small patch of it with steam. After this treatment the patch produced high grade wheat season after season until the fungi crept in again. It is only fair, however, at this point to say that many scientists have conducted soil sterilization experiments and a good number of them think that the beneficial results of sterilizing soil are due at least partly to other things than the destruction of parasitic fungi. At any rate they demonstrate that the plant food materials are not always exhausted when poor yields result.

REMEDIES.—Remedial measures should be directed toward getting seed and soil which are as clean as possible, and then planting under conditions favorable to the growth of the wheat and unfavorable to the growth of the fungi.

SECURING CLEAN SEED.—The first thing to do is to get a single variety suited to your conditions and save your own seed, because seed raised on your own farm is better adapted to your conditions than any other can be. If your variety is mixed and there is no suitable pure one in your vicinity, you can purify it by selecting heads of the kind you want from your field and planting the wheat so harvested by itself in a multiplying plot. Since wheat is self-fertilized, the crop in the plot will be pure. When selecting seed for the main crop, pick out the best part of the field, or have a special patch and harvest it without letting it get wet in the shock. Use canvas shock covers if necessary. If it gets wet, the fungi present as spores or in diseased kernels will grow over the sound kernels and infect them. The next precautionary measure is to fan the seed. Screening is not so important, although it will do some good and certainly no harm. The essential thing, however, is to get rid of the light weight grains; and screening will not suffice, because such grains are often bulkier than the heavy ones. Use a fanning mill and see that the blast is good and strong. After fanning, use the formaldehyde treatment in order to kill all spores clinging to the outside of the grains. Spread the grain on the floor or canvas and sprinkle with a solution of a pint of formaldehyde to fifty gallons of water until all is thoroughly moist, shoveling over repeatedly in the meantime in order to distribute the moisture thoroughly and evenly. Shovel into a pile and cover with sacks or canvas for at least two hours. A longer time is better and it will not hurt to leave twelve or fourteen hours, but after that time, the grain should be dried thoroughly or planted at once, for the grains are apt to start germination. Where large amounts are to be treated it is advisable to use a machine, several makes of which are now on the market and do satisfactory work.

GETTING CLEAN SOIL.—There is no paying method of disinfecting soil on a large scale. For getting clean soil, therefore, we must depend on general sanitary measures. (1) Rotate, using crops not related to wheat, and kill all quack grass. It harbors the wheat parasites. If you are already rotating perhaps you can lengthen your rotation a year or two. In a good many sections of the corn belt, rotations of corn, oats, wheat, clover, and corn, wheat, clover are followed. If now, instead of the clover, one year of clover and Timothy followed by a year of Timothy be introduced, the rotation is made a year longer. At present prices of Timothy hay this should be a paying change aside from the effect on the wheat crop, especially as it reduces the amount of plowing one-fourth or one-fifth. (2) If wheat straw is used for bedding, compost the manure well before applying to the wheat crop. If it is desirable to haul manure direct from the stable, let it be applied just as far ahead of the wheat crop as possible—the best place is on the wheat stubble. If scattered thinly, it will not prove as great a bother in the hay crop as would be expected, and it certainly stimulates the clover and Timothy. (3) Have the soil well worked so that it is compact below but mellow on top. A soil which has cavities near the bottom of the furrow slice, furnishes a number of moist chambers, which are ideal for the growth of fungi. A well packed soil does not furnish this condition. At the surface the sunshine, the aeration, and the alternate wetting and drying of frequently worked soil tend to kill off the fungi.

FAVORING THE PLANTS.—Sow thinly. Prof. Bolley states that a good plant every three inches in the row is enough. When seed containing infected kernels is seeded thickly, the fungi from them quickly infect the normal seedlings near. "The root diseases spread most rapidly along the drill row in thickly seeded grain." Use fertilizers where trial shows that it pays. Usually phosphatic fertilizers increase the yield and improve the quality of product by making the plants more tolerant of disease. They do *not* purify the soil. Nitrogenous fertilizers usually weaken the straw, and make the plants more susceptible to attack, this reducing quality and yield, although increasing the yield of straw. Drain wet places. Wetness of soil tends to produce rankness and softness of straw and added susceptibility to disease.

CONCLUSION.—Several of these practices advised for the control of soil and seed-borne diseases of wheat have not yet been put to the test of actual extensive farm use, although most of the experimental work has been done. Prof. Bolley has been accumulating results for several years; other workers have secured results which corroborate his; and there seems to be no reasonable doubt that his results are reliable and his conclusions correct for his conditions. But most of Prof. Bolley's work was done in North Dakota, where the ravages of these fungi are extreme. Further east and south, where the attacks are less serious, some of the measures advocated may not be so important. In Indiana, for instance, the advice given by the Experiment Station and the personal observations of the writer indicate that top-dressing wheat lightly with manure in the Winter and Spring may be profitable in spite of the fungus infection. Also, very thin seeding is apt to prove unprofitable, due to Winter-killing. The correct farm practice will vary considerably in the different sections of the wheat producing regions. It will depend on a proper adjustment to the relative importance of the diseases, the fertility of the soil, the climate, etc.; and must be worked out for each section separately. Such precautions, however, as proper rotations, thorough soil preparation, careful seed selection, and the disinfection of the outside of the seed can hardly be overemphasized, because they are important in all regions, oftentimes doubly so due to their beneficial effect for other reasons than disease control. C. A. LUDWIG.

WET OR DRY TREE PLANTING.

I WOULD like your opinion on two methods of orcharding employed by some growers in this section. One is the planting of young trees in heavy sod, with no working around them. The other is planting trees in holes dynamited in solid limestone ledge, with only one or two feet of surface soil. This method is being extensively used on one large commercial orchard, the manager of which claims to be an orchardist, and is selling stock in the company. I have had over eight years' practical experience in commercial orchard work in the Pacific Northwest, and have just lately come East to go into the same line of work and it may be that I do not know enough about eastern conditions to pass judgment on such practices. However, I cannot reconcile planting young trees in shallow soil in solid ledge, no matter what preliminary treatment is given, to my experience and knowledge of trees. On the other hand if there are any virtues in the practice which recommend it to commercial orcharding, I would like to know it, as I can buy this character of land cheap and start a paying venture with little money, or I can buy stock in some orchard company following this method. A. W. V.

Vermont.

As a general proposition we advise you not to buy stock in a commercial orchard, either the "unit" system or as a general company. There may be local exceptions to this advice, but without knowing definitely about them our advice is keep out. The plan of planting trees right in a sod without culture succeeds under favorable conditions. Mr. Hitchings in New York and Mr. Vergon in Ohio have clearly demonstrated the possibilities of this method. On our own farm we have one block of trees in sod that has developed into a fine orchard. Within 1,000 feet of this block are trees which were at the verge of failure until we plowed the sod and gave good culture. The successful block stands at the bottom of a hillside which is underlaid by springs. The water works down the hill and waters the ground where the sod trees stand. On the other location there is none of this seepage water; the soil is shallow and thin, and the trees suffer from drought. The cultivator was needed to hold the moisture. This sod culture will not be likely to pay unless the trees are put in *natural grass land*, deep and naturally moist, and in a region where the rainfall is heavy. From our experience we should consider it poor practice to set trees in sod on thin dry land, unless large quantities of mulching material can be cut and piled around the trees. We know of cases where thin rocky hillsides are planted in this way. These hills are not plowed or cultivated except in strips along the tree rows. In the swamps and valleys near these hills there is usually a rank growth of grass and weeds. This is cut, hauled out and piled about the trees, and in this way a fair growth is obtained. As for the plan of blasting holes in a ledge and planting trees in a shallow soil, our experience shows that in this way you can obtain a somewhat under-sized tree coming into bearing early and yielding fruit of very high color and fine quality. We cannot imagine a man selecting such soil from choice. We should think he would be driven to it through necessity—for deeper, moister soil is far better.

RENTS FOR POST OFFICE BOXES.

THE box rents at our post office have just been raised. Is the postmaster permitted to do this? Who has control of this matter, and have these rents been raised all over the country? J. S.

To settle this matter we wrote the Postmaster General and received the following letter:

In reply to your letter, I have to state that for the purpose of securing uniformity, box rent rates are based upon the gross receipts of the post offices and the size and style of the boxes rented. The schedule of rates adopted by the Department is enclosed for your information. If rates in excess of those by the Department are exacted at any particular post office and report thereof be submitted to this office, investigation will be immediately instituted to correct the rates.

A. M. DOCKERY,
Third Ass't Postmaster-General.

The schedule of rates fixed by the department is printed below. If higher rates are charged in your post office the thing to do is to send a report to Washington at once.

Box rent rates have been fixed heretofore upon no established basis, with the result that at certain large post offices rates are lower than at many small offices; that the charge for small boxes is in many cases higher than that which should be made for large boxes; that rents are sometimes collected at the same rate for boxes of all sizes; and that at post offices of like class, in the same vicinity, equipped with similar boxes, rents are collected at widely different rates. In order to remedy these conditions and to provide a definite and satisfactory rule for the collection of box rents the following schedule, based upon the kind and capacity of boxes and the gross receipts at post offices, has been adopted and will be strictly adhered to by the Department in the establishment of all box rent rates, from and after Jan. 1, 1907:

Gross receipts of post office.	Rate per quarter.					
	Call boxes small. (*)	Call boxes large. (†)	Lock boxes small. (*)	Lock boxes medium. (‡)	Lock boxes large. (§)	Lock boxes extra large. (‖)
Less than 500	$ .10	$ .15	$ .20	$ .25	$ .35	$ .45
$500 and less than $1,900	.15	.20	.25	.35	.45	.60
$1,900 and less than $5,000	.20	.25	.35	.45	.60	.75
$5,000 and less than $10,000	.25	.35	.45	.60	.75	1.00
$10,000 and less than $40,000	.35	.45	.60	.75	1.00	1.50
$40,000 and less than $100,000	.45	.60	.75	1.00	1.50	2.00
$100,000 and less than $300,000	.60	.75	1.00	1.50	2.00	3.00

$1,000,000 and less than $5,000,000	1.00	1.50	2.00	3.00	4.00	5.00
$5,000,000, and less than $15,000,000	1.50	2.00	3.00	4.00	5.00	6.00
$15,000,000 and upwards	2.00	3.00	4.00	5.00	6.00	7.00

* Less than 200 cubic inches in capacity.
† Capacity 200 cubic inches and upwards.
‡ Capacity 200 cubic inches and less than 500 cubic inches.
§ Capacity 500 cubic inches and less than 900 cubic inches.
‖ Capacity 900 cubic inches and upwards.

A Business Cow.

THE picture, Fig. 442, shows a good grade Holstein cow owned by D. G. Heigerd, of Rockland County, N. Y. In speaking of her Mr. Heigerd says:

"She is just plain Bess, without a number or pedigree, but producing 480 pounds of milk in seven days."

State Testing Soy Beans.

THE New Jersey Experiment Station believes that the Soy bean is one of the most valuable forage plants. It makes a hay that is nearly as rich in protein as Alfalfa. Some disappointment with this new legume has been due to the use of varieties that were not adopted to soil and climate. John H. Voorhees of the extension department is conducting 48 experiments in various parts of the State to determine adaptability of the leading varieties. Mammoth Yellow, Medium Green, Wilson, Ito San and Swan are being used in this experiment. Some of them doubtless are best adapted to southern Jersey and others to the northern half of the State. It is hoped that the results obtained next Fall will enable the station to advise farmers safely regarding the varieties that they should grow. D. T. H.

To make "big pumpkins" you must first have a variety which grows large naturally. Then pinch off all but one flower, so as to throw the full strength of the plant into one fruit. Then be sure the plant is fully supplied *at the hill* with plenty of water and available food.

THE ARMY WORM.

Its Life Habits and Distribution. Fight It!

PART I.

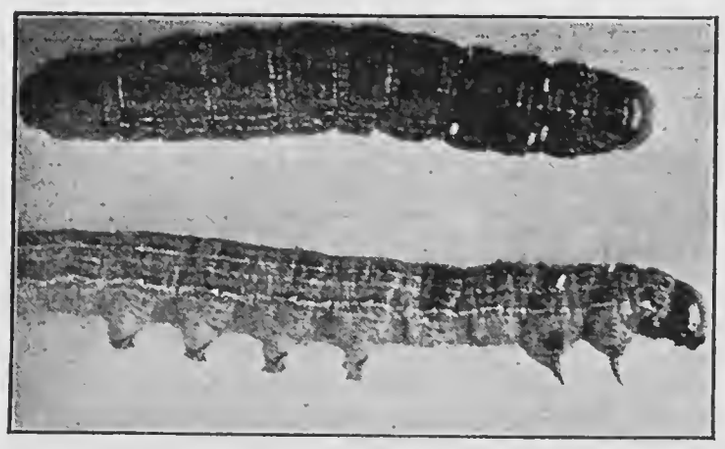
ACCURATE records regarding distribution in the present army-worm outbreak are not now at hand, but according to newspaper clippings examined, it has occurred in Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, Maryland and Michigan. It was reported as being particularly severe on Long Island, in Maryland, and in Michigan, and no doubt it has caused greater or less damage throughout all of the Northeastern

FEMALE ARMY WORM MOTH, NATURAL SIZE. FIG. 438.

States and the Middle West. According to one newspaper, the damage in Michigan was estimated at a million dollars.

FOOD PLANTS AND DAMAGE.—The chief damage is done to crops of the grass family, including the cereals and corn. The worms eat the leaf-blades and often the heads of the grass or grain, leaving only the stalks. Many oat fields in Connecticut this season, were thus stripped of their leaves; the heads were also eaten off and fell to the ground. The writer saw a five-acre oat field similarly injured in 1896, at Hartford; the caterpillars in marching to the adjoining field, literally covered the ground over an area perhaps twenty feet wide and more than a hundred feet long. Within this area it was impossible to walk without crushing a dozen or more caterpillars at each step. One could actually hear them crawl upon the ground. Thus when in search of food, army worms will attack fields of corn and many kinds of garden vegetables, which are not ordinarily, their first choice. In some places cranberries have been severely injured by them. Clover and Alfalfa are not often greatly damaged, yet in New Jersey in 1880, there were cases where the army worms seemed to prefer clover. They seldom attack trees and have only once been recorded as eating the leaves of fruit tres. The present season, at least in Connecticut, they were not sufficiently abundant to cause them to migrate from one field to another in large numbers; they were able to get plenty of food in the fields where they were hatched, and in most cases without eating all of it. Oats, barley, rye, wheat, grass, corn and millet were the principal crops damaged. Like cutworms, army worms feed mostly at night, and hide under something near the ground, during the day. When the worms are numerous and their food scarce, they are not able to satisfy themselves at night and therefore feed during the daytime.

WHAT IS THE ARMY WORM?—The army worm is the larvæ or caterpillar of an inconspicuous brown moth, belonging to a group known as owlet or Noctuid moths which includes the cutworms. Its Latin or scientific name is Heliophila unipuncta Haw., but for many years it has been called Leucania unipuncta, this name appearing in most of the pub-



ARMY WORMS SHOWING EGGS OF PARASITE TACHINID FLY, TWICE ENLARGED. FIG. 439.

lished accounts of the insect. The name unipuncta was probably given to the species because of the small white spot near the center of each fore wing. The common name "army worm" doubtless comes from the habit of the caterpillars when abundant; after devastating one field they march onward en masse, seeking another to devour. But whatever the name, the army worm is the same old pest, which for nearly two hundred years has exhibited occasional and destructive outbreaks. The Rev. Thomas Smith, of Falmouth, Me., wrote in his diary, June 27, 1743: "There are millions of worms, in armies, appearing and threatening to cut off every green thing; people are exceedingly alarmed." This was the first outbreak of which we have a record. Others have occurred in the years 1762, 1770, 1790, 1817, 1825, 1861, 1875, 1880, 1882, 1885, 1890 and 1896. There are two other kinds of army worms, the "wheat head army worm," Heliophila albilinea Hbn., and the "Fall army worm," Laphygma frugiperda S. & A.

WHY DO THESE OUTBREAKS OCCUR?—Where is the army worm, and what is it doing in all the years between these outbreaks? These are fair questions. The army worm is here all the time. It feeds as usual on the native grasses. We find a few moths around electric lights, in other years. But it does no damage because the caterpillars are few, and they are seldom noticed. It is only when extraordinarily abundant that they attack and injure cultivated crops. "But why are they abundant?" you will ask. It is the old and somewhat complicated question of weather conditions, and natural enemies. These factors, though existing in variable and uncertain ratios each year, occasionally form such a combination as to permit an outbreak. No one has yet been able to manipulate or control these conditions, like members of the stock exchange, in order to corner the market, to prevent an outbreak, or even to predict with any degree of accuracy when an outbreak may occur.

DISTRIBUTION.—Dyar's "List of North American Lepidoptera" gives H. unipuncta as occurring in

ARMY WORM FEEDING ON CORN, NATURAL SIZE. FIG. 440.

the Atlantic States. This publication also lists thirty-six other species of the genus Heliophila, 15 of which occur along the Atlantic seaboard. Slingerland states in Cornell Bulletin No. 133, that although a native of North America, the army worm is now known to occur in South America, England, Australia, New Zealand, India, Java and Madeira, but is not destructive in these countries.

Connecticut Exp. Station. W. E. BRITTON.

ARE MILK INSPECTORS STRAIGHT?

IN our vicinity there has been an almost complete cessation of complaint regarding inspection of cow stables by city milk inspectors for some time. The reason at first was that we got in touch with dealers in other cities, and the New York inspectors had little to do with us. Later, when New York got in competition, there was a discussion on as to whether the city or the State should do the inspecting, and farmers have an idea that this discussion held inspection somewhat in fear. Then the New York folks made charges against the State Department of Agriculture, charges which many believe were for the purpose of holding off the change to State inspection. I do not say that these are established facts, but there seems to be much reason for such conclusions. Whether this diagnosis of the case be correct or not, there is little doubt that we are having more trouble from inspection than for some time. It does not yet seem to be equal to that of earlier times, but is thought to be unfair in some cases. That State inspection appears to be now in abeyance, and no appearance of pressing the charges against the Department, goes to indicate that the object of the city has been accomplished. Those charges were serious, although answered by the Department, but they should not be dropped without some definite conclusions. If the city made the charges for a purpose, as some think, other than the one apparent on the face, then the Department should be exonerated and blame applied where it belongs. But it is not of any disagreement between the Department and certain city interests that I wish particularly to speak, but of some acts of inspection that are recent.

My own suspicion was aroused early in the Spring when in the office of one of the big milk concerns. An inspector happened to be there when I went in, although I did not know his identity at the time.

CHRYSALIDS OF ARMY WORM, NATURAL SIZE. FIG. 441.

He soon went out, and as he departed he remarked to the manager that if he needed any assistance let him know. The manager soon explained to me that inspection is now as it should be, and remarked that the inspector who just went out was a mighty fine fellow. If inspection is for the exclusive benefit of the dealer it is not as it should be. These remarks do not prove that it is for the exclusive benefit of the dealer, to enable him to buy milk at a lower price where he ought to pay for increased care and attention on the part of the farmer, but they set one to thinking. Along in June, when milk was flush, it is stated that a certain concern sent for an inspector to come. He came and scored down nearly all the dairies in one neighborhood, so that the 10-cent bonus could be withheld. At the same time the test went down, so as to save the other 10 cents that the company contracted to pay if the test met the requirements. Here was a saving of 20 cents a hundred to the dealer. This is as it appeared and is believed by the farmers. They found that they did not have to stand such a cut, and commenced preparations to leave the concern. This took till well towards July, or into the month. Then the manager found what was up and immediately took his horse and drove about to the patrons, offering to pay them from that time on both the test and the score. Most of the patrons stayed on but a few left. It does not leave a friendly feeling either toward the concern or the inspection.

I will mention one other instance. It has been claimed all along that inspection is more severe in the case of a coöperative creamery. I have never traced this out, but here is an instance that goes a way toward establishing the claim. At a certain coöperative creamery there was one patron who lived on a rented farm and refused to come up to the requirements of the coöperative, even when they were engaged in making butter. He was dropped, and went to a milk shipping station in the same town. The inspector came and gave him a fine score, although he had done nothing to clean up.

BESS, A GOOD GRADE HOLSTEIN. FIG. 442.

A few days later the farm changed hands and the new tenant fixed up what he could do readily, and was taken on by the coöperative. At about the same time the coöperative commenced to ship cream to the city, and the same inspector came back and inspected the patrons of the coöperative. All agreed that the inspection was much more severe, and in the case of the new man who had cleaned up, he was scored over 25 points below his predecessor in the same stable, but who patronized the big dealer who operated the shipping station.

H. H. L.

NEW YORK STATE NEWS.

FARM MANAGERS BUSY MEN.—There are 25 farm bureau managers in the State at this time and during the last six months, according to statistics recently published, they have visited 4,848 farmers. Of this number of farmers 864 are conducting some kind of experiments. Farm help has been secured through these bureaus for 112 farmers this Spring aud Summer. Survey records to the number of 111 have been taken. On 222 farms records and accounts of the farm bnsiness is being kept with the manager's assistance. The 25 farm managers have addressed over 300 farmers' meetings. In connection with the Department of Agriculture 25 cow-testing associations have been organized or are being conducted, in which over 15,000 cows are being tested. The business done by the coöperative associations, prompted by the bureaus, during the past six months amounts to $14,765. But it is difficult to set down in figures or estimate on paper the value of leadership and initiative exercised in rural affairs by these expert farmers.

CORTLAND FAIR AND SWINE EXHIBITS.—Having in view the recent communication from Commissioner Huson relative to the withdrawal of swine exhibits at the fairs, the Cortland County Agricultural society has set a very sensible example to other county fair associations by deciding to admit to competition such swine as has been vaccinated for hog cholera or are shown to be free and immune from the disease. A certificate to this effect from a veterinarian must accompany all entries of swine. Some societies are admitting only local animals known to be free from the disease while others will shut down on these exhibits entirely.

THE HOP GROWERS.—While the prospect for a good crop of hops in Schoharie County, still holds, yet the outlook is not quite as good as a week ago on account of insect depredations. Blue mold, lice, and honeydew are responsible for the changed situation. The vines have been sprayed but rains have made it less effective than is desirable.

NEW PUBLICITY BUREAU.—It is announced that Dean Galloway of the State Agricultural College will adopt a plan of publicity for the College similar to that used by the U. S. Department of Agriculture. The idea is to use the newspapers more largely, instead of bulletins.

CONFERENCE ON NEW APPLE-PACKING LAW.—There were but few present at the conference called by Commissioner Huson on Aug. 11, to discnss some of the features of the new apple-packing law. But there were lots of questions. What about the application of the law? How many inspectors will be necessary? Where shall they do their work? Shall they inspect while picking and packing is going on? Shall they inspect only at shipping stations, or at terminals and city docks? Can 50 competent inspectors be found, readily, who can interpret and apply the law? Will the law be stringently enforced? Is it permissible under the law to plate barrel or box? Who is the party to be held responsible for the quality conforming to the mark? Is it packer or seller? Must fruit sent to cold storage be stenciled according to the law the same as when sold for immediate distribution? What if the buyer lives in another State? Shall the grower guarantee the pack or the buyer? Would an iuspector have any right to inspect fruit at a shipping station or terminal that was packed under the United States law? Will marking a barrel 'Unclassified" be likely to secure for it a lower price? These are some of the questions that came up for discussion, and they will serve to show the uncertainty surrounding some of the provisions of the law.

L. L. Morrell of Kinderhook was chosen chairman of the conference aud said in opening the discussion that he believed the more the law was studied the more satisfactory it appeared, and that it seemed to him that it would work out greatly to the advantage of the apple business. He had found some who would pack under the United States law and some will mark the fruit "Unclassified," this owing largely to the uncertainty of just what the new law demands in some of its provisions. On the whole he considered the law the best thing that "had ever happened to our fruit growers." Mr. Morrell was asked if the law permitted a man, if he cared so to do, to plate his barrel with the finest fruit allowable in the barrel under the classification of "A" or "B." He believed that the law permits it, and that is one thing he did not like about it. Not all present shared this opinion, as to the permission of the law on this point. As to who is to become responsible for the pack, it was conceded that the packer or agent or buyer, was the responsible man. If a grower packs his own fruit he must put his name on the barrel. If buyer or agent for another packs it, or if it is packed by his authority, then his name must go on the package. It makes no difference if the fruit is to be shipped to a purchaser residing in another State. The law applies. The problems which the Commissioner of Agriculture particularly desired an opinion upon was the inspection of the fruit to ascertain if the packing was done in accordance with the law. It was suggested by one that the inspectors should visit the orchards when the paekiug was under way, but this would necessitate a large number of inspectors to cover all orchards in the State. However, it was not considered wholly impracticable. Another suggested that the inspection should take place at the shipping station where one inspector could do the work of many in the orchards. This idea appealed to all present. No doubt but that inspectors will be found at the larger shipping stations. Also at terminals, particularly steamer docks. In the absence of a legal opinion on the subject, it was the consensus of opinion that an inspector could make no inspection of fruit packed under the United States apple grading law. But apart from that exception all apples must be packed under one of the classifications called for by the new law, namely: New York Standard Fancy grade; New York Standard "A" grade; New York Staudard "B" grade or, lastly, "Unclassified." It was stated by representatives of the Department of Agriculture that it had been reported that buyers in the cities had advised growers and dealers that the new law would not be enforced and to pack "just as they always had." We would not advise growers and buyers to bank too much on that statement. While injustice will be done no honest packer or grower who tries to conform to the law until he fully understands it, we imagine that the dishonest grower, if there be such, or the dishonest packer, if there be such, will find an inspector camping out very near to his place of operations and will undertake to see that the law is euforced to the letter.

J. W. D.

CROP REPORTS.

Dairy cows sell for from $60 to $100; steers (fat) from 7 to 8 cents a pound; hogs 8½ cents; poultry 12½. Hay $10; wheat 83; oats 32 to 38; butter 25; eggs 18. Milk sold to condensery, $1.30 for July. Apples usually sell for $1 aud $1.50 a barrel; peaches $1.25 to $1.50 a bushel; plums $1.50 to $2. Strawberries sold for 10 cents a quart and raspberries for 12½. Potatoes sell in the Fall for from 35 to 50 cents a bushel. Very little gardening done in this vicinity.

Michigan. J. A. W.

August 6. Haying all done, crops about one-third larger than for several years; have had frequent showers and pastures are good. Corn, potatoes, oats and buckwheat are looking well. Apples, pears and small fruits are full crops, except plums. No late frosts last Spring to kill blossoms. Early potatoes $1.25 per bushel at the stores; eggs 26 for white, 24 for brown; butterfat for June 28¼ cents net; broilers 18; old hens 14. This is one of the largest poultry sections in the State, several thousand pullets being sold from here each year. B. H. G.

Jefferson, N. Y.

Fresh cows, in my neighborhood, $50 to $85; in western Washington, $80 to $150, net cash price $50 to $150; veal, per pound, deduct 35 cents freight, per animal, commission paid by storekeeper, 12 cents; fresh milk, in my neighborhood, for navy yard and adjacent towns, 18 to 20 cents a gallon at the condenseries, no freight paid on milk to navy yard towns; collected by dealers who retail milk at 12 quarts for $1; $1.40 to $1.60 at condenseries. Potatoes, cash or trade, at local store, 1½ cents per pound; eggs, local store, 25 cents; butter, local store, 30. Old hens, deduct 35 cents freight, per crate; commission paid by storekeeper, 15 cents per pound; Spring chickens, 16 cents. Poultry to meat market, Seattle, where storekeeper buys meat. Pork, dressed, nine cents; apples, bushel box costs 13 cents, commission 15%, 50 cents to $1.50 gross. Pears $1 gross. Loganberries 90 cents gross, crate of 24 pint costs 18 cents, commission 15%, 75 cents to $1.25 gross; rapsberries $1 gross, 75 cents to $1.25 gross. Strawberries 75 cents to $1.25 gross. Bran $26; shorts $28; middlings $35; rolled barley $26; oats $31; corn, whole, $39; corn, cracked, $40; wheat $34; Alfalfa $16; Timothy $20; straw, wheat or oat $12. (Quotations from local storekeeper) not produced here. Great quantities of poultry produced here; the leading local industry. Question to local storekeeper, "Anybody really making money on poultry?" Answer: "No." S. E. P.

Kitsap Co., Wash.

COMING FARMERS' MEETINGS.

Thirty-ninth Annual Convention of the American Poultry Association, to be held at Chicago, Ill., August 8th to 15th, 1914, inclusive.

Northern Nut Growers' Association, annual convention, Evansville, Ind., August 20-21.

National Paving Brick Manufacturers' Association, eleventh annual convention and paving conference Buffalo, N. Y., September 9, 10, 11, 1914. Secretary Will P. Blair, 832 B. of L. E. Bldg., Cleveland, Ohio.

National Dairy Show, Chicago, Ill., October 22-31. The following meetings and conventions will be held in connection with the show: American Association Creamery Butter Manufacturers, Oct. 26. Holstein-Friesian Association of America, Oct. 26. International Milk Dealers' Association, Oct. 26 and 27. Conference, Secretaries of State Dairymen's Association, Oct. 27. Official Dairy Instructors' Association, Oct. 27. National Dairy Union, Oct. 28. American Dairy Farmers' Association, Oct. 28. Council of the National Dairy Show, Oct. 28. National Association of Creamery Managers and Owners, Oct. 28. American Jersey Cattle Club, Oct. 28. National Association of Ice Cream Manufacturers, Oct. 28, 29 aud 30. International Association of Dairy and Milk Inspectors, Oct. 29. American Guernsey Cattle Club, Oct. 29. Congress of Marketing, Oct. 29, Milk Producers' Association, Oct. 30.

New England Fruit Show, in connection with the Rhode Island Fruit Growers' Association annual meeting, in Providence, R. I., November 9, 10, 11 and 12, secretary A. M. Parmelee, Norwood, R. I.

National Grange, annual meeting, Wilmington, Del., November 11-14.

Maryland Week Exhibition, State Horticultural Society, Maryland Crop Improvement, Dairymen's and Beekeepers' Associations, Baltimore, November 16-21.

Annual Show of the Paterson, N. J., Poultry, Pigeon and Pet Stock Association, November 18-21.

Indiana Apple Show, Tomlinson Hall, Indianapolis, Ind., November 18-24.

LITTLE TOMMY, of the city, visiting his country aunt and uncle, declined to be satisfied until he had fished in the near-by stream. To this end he made the life of his uncle a veritable burden by coutinued coaxing to procure him the necessary bait. One afternoon Tommy spied him plowing diligently. With a whoop of joy the would-be sportsman rushed forward to his uncle's side, but here grew suddenly thoughtful. "Gosh, Uncle," he exclaimed, gazing speculatively up the long stretch of furrowed ground, "ain't that about enough worms?"—Everybody's.

"For the Land's Sake, use Bowker's Fertilizers; they enrich the earth and those who till it."—*Adv.*

How to Get Lumber at Mill Prices Write to us for prices on lumber delivered to your station. We can furnish you with stock shipped directly from our yellow pine mills and save you a large amount in the cost of your lumber, and supply you with better lumber than sold by a great many retail yards. The capacity of our yellow pine mills is over 75 million feet per annum, and we carry in stock over 25 million feet of dry bright lumber from which to fill orders. If you contemplate building, write us now for information.

Mill Work We can furnish Doors, Window Trim, Moulding, Porch Work, Hardwood, Flooring, also Building Paper, Plaster Board, and Roofing of all kinds.

Home Owners Carpenters Contractors Procure our mill prices before you buy. We will quote wholesale prices on all material delivered to your station. Special bills sawed out. Estimates furnished promptly.

Club Orders We can ship lumber in the same car to two or more parties, whenever requested. You can club with your neighbors and get carload rates making a big saving on small orders.

Send No Money We ship directly to any responsible party on approval. You can unload and inspect every piece of the shipment before paying us a cent.

Write Today Write to us now for full partieulars. We can save you money and furnish you with guaranteed grades of lumber. A postal card from you will bring full information regarding our liberal method of doing business. Write today.

Manure for Currants; Cabbage Maggot.

ON page 925 appeared an article on "Cover Crop for Blackberries," which I shall try this year. I have about 100 currant bushes, from which we picked 112 quarts, this, their third bearing year. Land is a sandy dry soil, inclined to be gravelly and pack hard, unless it is frequently cultivated. These bushes have had a shovelful of hen manure each Fall, worked in around the bush. Part of the bushes are thriving, and some, about 30, during the dry spell in June, were yellow, and had but few berries. Would you advise me as to the treatment for them all? They were sprayed with soluble oil in the Spring and all dead wood and too thick branches were cut out. Many branches, laden with fruit would wither and die and the stalk would be all eaten away near the ground. 2. A neighbor of mine lost over half of his early cabbage. When good size, they would die, and on pulling up the plant, white worms or grubs would be in clusters on each root. Will you tell me the cause, and cure? P. T. B.

West Springfield, Mass.

It is a mistake to apply manures to bush fruits in the Fall with the idea of getting the best, and in many cases even any results from it, particularly if the soil is sandy, or gravelly, or both, as the leachings are carried below and beyond the reach of the feeding roots long before Spring. Currants do not root deeply, most of the fibrous or feeding roots being quite near the surface, and whatever is applied in the way of manures, should be given them in early Spring, and during the fruiting season. Hen manure is an excellent fertilizer for currants, but should always be applied in March, as early in the month as it is possible to work it into the soil, and only in limited quantity. A small shovelful will be ample for a three or four-year-old bush. After the fruit has set, a mulching three or four inches deep of coarse stable manure around the plants will be very helpful in carrying the crop through to maturity, particularly if the weather is dry. Do not apply much hen manure to these sickly plants next Spring, but give them a liberal supply of raw bone meal and a little muriate of potash, say a small handful scattered around each bush worked into this soil, and before hot weather sets in mulch the plants well with coarse stable manure. The branches that died were killed by the stem borer. Every plantation suffers more or less from them, and the weakly or sickly plants seem to be the favorite objects of this borers' attack. All branches showing their presence should be cut out and burned as soon as noticed or the borers should be hunted out and killed.

2. This cabbage was infested with cabbage maggot; this insect is found in almost every part of the country, wherever cabbage is grown and is one of the worst and most destructive enemies the cabbage is subject to. It being an underground insect its presence is never suspected until the leaves begin to wilt. Many remedies have been recommended but none of them have proven very successful. The insect is always present in greater numbers in ground that has been heavily manured with stable manure, the mature insect, or fly, selecting fermenting manure as a favorite breeding ground. Many cabbage growers have dispensed with the use of stable manure in the production of this crop, relying altogether on chemical fertilizers, and consequently have but very little loss from the maggot. Heavy liming will very materially assist in reducing the damage from maggot. It will be quite helpful in most cases to remove the soil from around the stems of the plants and apply a small handful of fine lime around them, three or four weeks after they have been set out. Early planting will also be of advantage, as the plants will be too large to suffer much injury, by the time this maggot arrives. Rotation of crops will be helpful in lessening the extent of damage from the root maggot and other damaging agents to the cabbage. K.

Scientific Bulletins.

YOUR July 25 issue contains a number of very good things. The point that farmers will quickly and gladly furnish better milk *if they are paid to do so* is something that needs to be impressed on city people. Your idea of a double series of bulletins, page 948, looks good. I have in my desk one I have been looking over from a professor. He had accumulated a fine lot of material, but it was not presented in a way to appeal directly to the farmer who needs most to be reached, the one at or below the average.

New York. DANIEL DEAN.

Cleaning Out Bats.

ON page 927 L. S. complains of bats in his garret. I should, if troubled, go after the bats just as the health officers do the rats in vessels; kill them with fumes and bury the remains. If he will close the windows in his attic and stuff the chimney full of rags or paste a newspaper over the opening, it will be ready to get busy with. Operate by daylight so you are sure all the bats are inside, and rig up a line to two windows so they can be opened from the ground to let the fumes out when the job is done. The cannon to do the shooting should consist of a tub with a little water in it, and an island made of stones or bricks in the middle. On this Robinson Crusoe habitation, put an old iron pot and some live coals, and put in a good liberal supply of sulphur, then "git a move on yourself," and exercise a little patience. If the pot turns over, the water will put out the fire, so it is safe. At the end of, say an hour, pull the two windows open and allow the fumes to escape, but not directly into any pet tree or you will ruin the foliage. What few bats may not be dead will be so near it that they can be gathered up and buried with the rest. It will also kill the bugs, which probably make life miserable for L. S., as that is the way with a bats' roost; they are always full thing that has lice on it, plant or breathing creatures, and will do the work. of bedbugs. The sulphur will kill every-

If for any reason the sulphur is objected to, I believe, a sprayer with a good charge of caustic potash or concentrated lye solution made very strong, or even a very strong lime-sulphur solution, applied liberally to the batty festoons would kill them or run them off.

Alabama. M. A. P.

STOP the holes where they get in and clean up the attic. I knew a man who got two wagon-loads of Peruvian guano out of his attic, made by leatherwing bats. The house had not been occupied for a long time, and the excrement was up to the top of the upper joists. The stench was so great that he could not stay in the house. They can get through a very small hole. G. Q. P.

Virginia.

I AM interested in answers to L. S., Sullivan Co., N. Y., who asks: "What can be done to get rid of bats?" We live in an old-fashioned house, with attic in middle of upper story—bedrooms partitioned off north and south of it. We cannot use them in the Summer as the bats take full possesion and in Winter the foul odor sticks in spite of old-fashioned whitewash. H. T.

Rhinebeck, N. Y.

A New Grass for Louisiana.

A BULLETIN from the Louisiana Experiment Station at Baton Rouge gives an interesting account of the Paille Finine grass, which promises great things for Louisiana farming. This pamphlet is written by Prof. F. M. Tracy, a special agent for the U. S. Department of Agriculture. It seems that this Paille Finine grass, Panicum henitonum, is distributed over most of the open prairies of Southern Louisiana. It is rare on the salt marshes and timber lands, and also rare on lands which are high enough to be cultivated in sugar cane. Its best growth appears to be made on land which is from one to three feet above the ordinary water level. The grass seldom produces seed and its spread is almost wholly by means of long rootstocks. Prof. Tracy estimates that there are in the State of Louisiana close to two million acres under this grass, most of it being found in the parishes of Cameron, Terrebonne, and Lafourche. The grass ranks very high in feeding value, specimens grown at the Experiment Station running close to 10% in protein, 42% carbo-hydrates and something over 2% fat with 5% of ash. The following statement shows how this grass is used in Louisiana:

"Planters at Lockport and Morgan City who have used the hay extensively in the feeding of mules were emphatic in their statements that they preferred the hay to that made from Timothy, as less is needed to keep the animals in good condition. At Houma, in Terrebonne parish, I found one planter who cuts a large acreage, and who uses the hay in making balanced rations for his mules. The freshly cut grass is taken to the central station where it is run through an ordinary feed cutter, and then through a steam-heated, revolving cylinder which dries it thoroughly in about an hour. It is then ground, mixed with 'blackstrap' or some other carbonaceous concentrate so proportioned as to give a properly balanced ration. In proportioning the materials used he finds the paille finine grass to be nearly equal to Alfalfa in nutritive value, and makes his mixture accordingly. He has about four hundred mules on his plantation, and they were in decidedly the best condition of any which I saw on the entire trip. He also finds a ready sale at satisfactory prices, for all the feed he is able to prepare."

This is certainly a novel scheme for handling forage but there seems to be a large demand for the grass, and when fed in connection with the waste molasses from the Louisiana mills it seems to give promise for a business in stock food production.

FARMERS' FAVORITE ENGINE

Is all that the name implies. It is built for service. Light in weight. Easy to move from one part of farm to another. Built by skillful workmen and of best material. Perfect Hopper Cooling System. Built in sizes 6 to 10 horsepower. Other sizes and styles. Equipped with magneto. Can be mounted on wagon. Lack of vibration is a notable feature of this engine. **20 YEARS of experience in building satisfactory engines for farmers is behind every FARMERS' FAVORITE.** We have never had a dissatisfied customer in this time—a record to be proud of. If you need power for any kind of farm work, it will pay you to investigate the merits and economy of **FARMERS' FAVORITE ENGINE.** Write us for further information and prices **TODAY.**

Hope Farm Notes

THE CONNECTICUT POULTRY MEETING.

PART II.

THE CONTEST.—The picture on page 1041 shows how the egg- laying contest is laid out. The hens are kept in double houses, two pens of 10 each to the house. Each pen of birds has a small yard, and on pleasant days they come and go as they like. My "scrubs" are in the house with the Silver Campines—the two pens have been having a close race. The hens help themselves at will to a dry mash and shells, water, charcoal and grit are before them. A self-feeder for grain makes them work for that part of their ration. They are all handled alike, except a few pens which are fed in various ways as an experiment. The houses are kept clean and the hens are carefully watched for injury or disease. At such a contest it is necessary to devise a plan which will be reasonably fair to all in feeding and care, and enable one man to care for a large number of pens. In each house are five trap-nests. When the hen goes on to lay the nest closes and shuts her in until the attendant comes and releases her. As each hen wears a metal band on her leg, carrying her number, the egg is marked and the record made at once on a printed slip tacked up in each house. Sometimes the nests are all occupied when a hen wants to lay, or the hen may be lazy. In that case the egg may be laid on the floor. It is credited to the pen, but of course the individual bird has no credit.

IS IT FAIR?—I do not see why not. Some breeders complain that this system of feeding favors the Leghorn too much. The strange thing about it is that the same complaint has been made by Leghorn men, who say this scheme favors the Wyandottes. It seems to me this plan is as fair as any one could well devise. The contest is located at the top of a high, windy hill, very cold in Winter and in all respects a Spartan test for Mrs. Egg Layer. A hen that can make a good record under the conditions at Storrs is a first-class practical hen, tested and tried not only for egg production but for endurance. That, I take it, is what we want rather than some condition where hens are pampered and petted for enormous records. For example, some of the standard Wyandotte men seem to think the contests are not fair because their birds must be fed and handled in a certain peculiar way in order to do their best. Yet in all contests from a horse race to a legal battle between lawyers, the contestant must take conditions as he finds them. When you sell a man a sitting of eggs you can hardly expect to send a man along with the eggs to explain how to feed the chicks. In this world all things must take their chance without special favors if they are to continue true and strong. Therefore I think this contest is the fairest place to test the true qualities of a laying hen. I think the time is coming when a performance at such a contest will be demanded by shrewd buyers. I do not care so much what a hen does at home under petted conditions. Let her get out in competition with other hens, and show her qualities without any "special privilege."

CASTING OUT DRONES.—The picture shows a typical scene in the contest enclosure. Little groups of people formed in front of the houses and discussed the hens. Each one had the last week's laying record, and as the houses are all plainly marked it was easy to study any particular pen. Tom Barron had agreed to give exhibitions of his method of selecting layers. A great crowd followed him about—so great that it was impossible for half of the people to watch Barron at work. So he climbed upon the roof of the henhouse, and the hens were passed up to him. Immediately the roofs of nearby houses were crowded with hen men, who thus secured a reserved seat. When Tom Barron made his speech at the church he surely did not know what to do with his hands. Up on that henhouse roof, however, those hands were mighty eloquent. As one man put it.

"Barron took a bird in his hands, gave her a twist or two, ran his fingers over her, held her up for a good look, and told nine times out of 10 where she stood in her pen record. He can make those hands of his hear and feel and see and talk. Mine can hardly *feel*—let alone the rest!"

Mr. Barron seemed to look at the toes and legs first, apparently to get an idea of their color. He noted whether the legs were placed wide apart. Then he studied the head, comb and eye. Then his hands ran all over the hen, back, front and at the side, testing the lines at the back, the shape of the breast bone, the length and breadth of the back. Then he held her up for one last wise inspection, after which he told with surprising accuracy how the bird stood in her pen record. When he looked over my "scrubs" I notice that he got down to notice how the hens walked and how they stood naturally on their feet. This seemed to be an essential part of his plan, and he was at a disadvantage up on the roof where he could not see the hens walk. At any rate it was a remarkable performance, and proved most effective with the company. For here was a man actually casting out drones—yet having had no chance to study them or know of their pedigree. In half the contest pens the record had been kept down by drones. About half the birds had laid well, but a few lazy drones had ruined the chance for any show for the prize. If these drones had been cast out by some master's hand the pen record would have been increased by 25 per cent. in many cases. This fact came home forcibly to this crowd of hen men. Profit lies not alone in breeding and feeding, but in casting out drones!

DRONE BIRDS.—I think one reason for the success of Mr. Barron's birds in this contest is the fact that they have laid uniformly with no individuals which can be called drones. My understanding is that the Wyandottes are sisters or half-sisters from pedigreed utility stock carefully selected by exterior tests. Evidently true sisters of the same breeding may vary in their egg-laying ability—due to peculiarity of growth or development. Mr. J. F. Francais has a pen of Barred Rocks, which contains three or four remarkable layers. If all the birds in this pen were as good as the three best ones there would be no stopping them from taking the lead. There are a number of fine-looking birds in the contest which thus far have not laid an egg, while others have laid less than a dozen. I asked several owners of leading pens how many of their birds they would select for next year's breeding. The replies ran all the way from two to five. Not one that I talked with expected to use the entire pen, for the trap-nesting had developed several drones or near drones that showed no superior qualities to hand on to their daughters. This presence of drone birds in nearly every pen was the thing which caused most thought and comment at the meeting. For the first time, I think, at a gathering of this sort it became the dominant question. Mr. Barron evidently knows how to cast out a drone. With him it is the same sort of instinct which enables a good banker to reject a poor risk, a good carpenter to select the right lumber, the shrewd lawyer to go right to the vital part of his case, or the good editor to know quickly whether "copy" is suitable or not. No man can teach instinct to another. The most skillful anatomist in the world might name every bone, joint and muscle in Barron's wonderful hands, but he never could tell how he separate the drones from the layers. I found other men in the crowd who could do much the same work—each having his peculiar system. I find that they did not agree as to the particular form of a superior layer, but they seemed to select the bird through some *instinct* or long-formed habit of observation. Evidently a man must know how to do it if he expects to excel with hens.

BREEDING UP.—I am sure that Mr. Barron convinced everyone who heard him that he is giving an entirely straight game with his Wyandottes and Leghorns. Starting with American Wyandottes, he has simply been guided by what the trap-nest told him, and what his hands corroborated. Unquestionably the English Wyandottes are of a different type from the American standard, but this is not due to bringing in new blood, but simply to the development of the egg-laying quality. It seemed to be the conviction of most people. I talked with that it would be better to breed these English strains of Leghorns and Wyandottes by themselves, and not mix them with the best American blood. The latter is a different type, and the two may not mix well. The meeting developed a new value for the egg contest aside from the pen or individual records. Men went from one pen to another comparing the egg records—one high, another low—and began to ask themselves:

"Why this difference?"

What is there about this pen or this hen which makes this evident difference in egg value per year? This thing was never brought home to some of these people so forcibly before. They cannot forget it, and it will force them on to study out the principles of breeding and selecting. Another future that I see in these egg-laying contests is in making them the exchange for buying and selling high-class utility stock. I expect to see the time when breeders of utility stock will go to such a contest and bargain for pens or individuals on the strength of their egg records. This will be following the course of fairs and tests where cattle are sold on their record. These things are sure to come as soon as "men can be convinced" that "breeding up" a flock of poultry by using pedigreed stock is anywhere near as sure a thing as the use of pure blood in cattle breeding.

THE SCRUBS.—No, we have not forgotten them. They were right there, happy as larks and very much more productive. They laid seven eggs in honor of the day. They had outlaid their house companions, the Silver Campines, by 13 eggs at the end of July. Various people told me they are not "scrubs" at all. I have explained several times where I got them, but these critics do not seem to agree as to what a "scrub" is. If they will only agree and tell me what they mean I will enter a pen which ought to satisfy them.

The Home Acre.

NOTES FROM A MARYLAND GARDEN.

THE John Baer tomato, which I mentioned in my last notes, is the monumental fake in seeds this season. It was claimed to be the earliest ever. In fact I picked the first ripe fruit the same day that I picked the first from the Brimmer, one of the large Ponderosa type. The Louisiana Station says that it is simply Chalk's Jewell renamed, but with me, while it does look like Chalk's Jewell, it is a much later tomato. Having paid $1 for a paper of the seed I gave it more space than other really early tomatoes. The Earliana was ripe two weeks ahead of it, and I would have been better off without the John Baer, if the space had been occupied with Earliana.

I have always had a fancy for testing new tomatoes, and have tried nearly all of them from the time when I paid Col. Waring $5 for 20 seeds of the Trophy, the forerunner of all the modern tomatoes. Before the Trophy came out the best smooth tomato we had was the Tilden. This was smooth, but with great seed cavities, and not meaty, as the best tomatoes now are. The Trophy was the first successful effort to get the big Monmouth Chihuahua tomato inside a smooth skin, and gave us the meaty character of the Mexican tomato without its creases, and this meatiness and small seed cavities have been the aim of all tomato breeders, until now there is hardly a really new feature that can be added to the tomato of any of the good strains. The object now should be to eliminate any of the hard core.

Among the tomatoes I have tried I give the preference among the pink sorts to the Globe, and of the red the Success. While it is interesting to have a few of the Monmouth or Ponderosa type, the medium-sized and smooth fruits give the larger number per plant than the mammoths. In fact it seems to be a law in nature that when we increase the size of fruits we invariably decrease the number on the plant. The little pear, plum and cherry tomatoes will make 10 times as many as Ponderosa. The Big Susquehanna peach never makes a great crop of fruit, and the Montreal Market cantaloupe will not make near as many as the Rocky Ford.

One of the most useful of the cabbages in my garden is the Succession. The first sowing of these is now coming into head right after the disappearance of the Charleston Wakefield and the Copenhagen, and a second sowing promises to come in in August. The Copenhagen Market cabbage is a fine second early, but it will not answer for Fall sowing and setting, as it runs to seed too badly. But sown in a frame in February it comes in very nicely with the Charleston Wakefield sown at same time, makes a fine head, and is as good a second early as one could wish for.

The Portland Market corn from an Oregon seedsman was the earliest corn I have ever grown, but it was more affected with smut than any corn I have ever grown. Nearly half the crop was ruined by smut, while I seldom have smut in my garden on other any later sorts. Country Gentleman and Stowell's Evergreen are still the standard varieties for the table in this climate. It is very nice to have a few extra early ears, but for quality and good size the two sorts named have never been excelled in my experience. Of course we can get rather large ears with the Mammoth and the Egyptian, but in quality they do not compare with the Country Gentleman especially.

Berger's Green Pod bean is now giving us a plentiful supply of string beans of large size and great tenderness. It is a great improvement on the old Dutch Caseknife, and as I give it a five-foot width of chicken wire netting to climb on it seems to run a little higher than the Caseknife, and the dry beans are as good as the navy beans, which do not thrive well here. W. F. MASSEY.

Maryland.

These Trees Rob Crops.

MUCH of my land lies beside a neighbor's woodland. This timber shades my fields and keeps me from raising a paying crop for many feet. How can I overcome such a condition? Perhaps roots rob soil of all fertility and moisture. Do the trees do more harm through the roots than by shading? I think they do, and propose to dig a ditch along the line fence and cut the tree roots. How deep should the ditch be? Would the scheme be practical financially? I do not know the cost of digging a ditch where there are many roots. E. H.

Maryland.

We should say that such timber operates in three ways to injure crops growing within a rod of it. The roots come out into the soil and take moisture and plant food. The trees shade the land and prevent air circulation or drainage. We should say that the timber roots are responsible for about 40 per cent. of this damage. A ditch four feet deep will help somewhat, but some timber roots will run down under it. If the ditch can be dug so as to act as a drain it may pay aside from cutting off the roots. It will not prevent all the trouble, however.

Moving Bees.

HOW can I change bees from one hive to another? A swarm came to me, and I put them in the only hive in the neighborhood. It is a poor one; would like to put them in a new one, but do not know how or when. They are my first bees. MRS. F. G. S.

Skaneateles, N. Y.

First, fit up your new hive with frames and foundation, or full sheets of brood comb; then, after smoking the bees in the old hive on any bright day, remove the cover of the old hive and set your new hive, without its bottom, on the old hive in the place of the cover. If it does not fit bee-tight, use some narrow strips of wood about the edges to make it fit temporarily. With a stick drum on the sides of the old hive until you have driven practically all the bees up into the new one; then remove the old hive, putting the new one in its place on its own bottom board. Set the old hive a few feet to one side, turning its entrance in another direction from that it originally had, and after three weeks drum its bees up again into an empty box placed over it as your new hive was at the first drumming. This will get the bees that have hatched after your first drumming. After getting them into the box, smoke the bees lightly in the new hive and dump those from the box in front of the entrance; they will run in and join the colony in the new hive. The old hive can now be broken up and its honey removed. If in your first drumming you have secured the queen in the new hive, the bees will probably stay in their new home; if you have not, they will return to the old hive and you will have to repeat the operation; take plenty of time and do a thorough job. If you prefer, you can set the old hive to one side, place the new one in its place after having put frames and foundation in it and drum the bees from the old hive into a box inverted over it in place of the cover. Carry the bees in the box to the new hive and dump them in front of the entrance. Repeat the drumming after three weeks as before to get the newly hatched bees. M. B. D.

Will Buy the BEST Four Cylinder Motor Car Made for 1915

Fully equipped in every respect, Electric Self Starter, Electric Lighting, Power Tire Pump, and every one of the latest devices to secure comfort, accessibility and reliability.

The year 1915 will not only be a Mitchell year, but it will be famous as a year in which the Mitchell establishes another standard of values in automobile building.

Those who have seen the new model — especially dealers — are not only enthusiastic, but are clamoring for the first cars from the factory.

Our Vice-President and Chief Engineer, John W. Bate, who designed the original Mitchell, designed the "1915" from stem to stern and all his ingenious ideas and practical engineering innovations have been utilized.

The result is a car that beats them all—at a price $500.00 less than anything approaching it.

In fact there is no comfort, no "safety first" appliance, no accessory that adds to the enjoyment of automobile riding that will not be found in this car.

Over 95% of the car is made right in Mitchell shops which cover acres upon acres of space.

No detail is skimped — everything is weighed, judged, measured, tested with critical correctnes which gives the great *service* quality for which the Mitchell is famous.

Read the specifications in another column.

Compare them with any other car and you will find the most in the Mitchell. But after all don't judge the new Mitchell until you've sat at the wheel of the new model—until you get the **personal touch.**

We invite you to get this **personal touch** at our expense. We'll put a car at your disposal.

In the meantime send for the new literature which tells the whole story. Ask for Book 121.

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York
HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 75 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

THE New England Fruit Show will be held this year at Providence, R. I., on Nov. 9-12. The local fruit growers' association will help. Rhode Island has made some splendid fruit exhibits in former years, and the display this year will be finer than ever. When you come to think of it the Southeastern part of New England has given the world a group of the finest apples now grown. These varieties are grown to perfection at home, and the Providence show will bring out some remarkable fruit. We have for years claimed that New England can produce finer apples than ever were seen on the Pacific Coast. Providence will prove it!

*

A WISE old farmer who has followed the discussion about the value of the station bulletins sends us a clipping from an old magazine. This states that there is more knowledge now in the world than can well be handled, but what is lacking is a method of spreading it out where people can use it. It is something like the distribution of food. There is plenty of it produced, yet through faulty distribution there may be hungry people in the city, while 100 miles away food is wasting because the price offered for it is too small to pay the cost of gathering and shipping. No one will deny that our colleges and stations have added greatly to the knowledge of agricultural science. Yet the shortest trip out where farmers work for a practical living will show how little of this knowledge has been made available. What can be done to get this knowledge out to the people? There you have one of the big problems of agricultural education. As you know, our suggestion is to let practical farmers write some of the bulletins.

*

IN a quiet way, and without organization thus far, efforts are being made to increase the wheat crop in the New England States. Years ago the New England people produced most of their own flour. In 1879 the New England States grew 1,227,037 bushels of wheat. In 1909 this yield had fallen to 114,998 bushels. Vermont and Maine have been the wheat States—the two producing 99,206 bushels in 1909. There are two reasons for the new interest in wheat growing. The poultry industry has increased rapidly of late, and wheat is a necessary food. Most henmen have large farms with considerable waste or unproductive land. Why cannot this be utilized for growing wheat? It is also true that many farmers believe that this country is approaching a period of very high grain prices. The European war will, finally, bring the world to our doors for food, and there is a general feeling that now is the time to increase our crops of bread-making grains. Our own opinion is that there will be greater profit in growing the native flint varieties of corn on the New England hills—rather than in sowing wheat.

*

THERE is good work to be done through the farm bureaus, improvement societies or whatever name you may call them. The theory of securing the aid of some expert in scientific farming to act as adviser is sound, as is the theory of organization. There is but one way, however, as we see it, for these organizations to succeed. That is for the farmers themselves to take hold of the organization, finance it fairly, and then control it for practical purposes. Young men, untried in practical farming, however bright and well read they may be, cannot be expected, by their own efforts, greatly to change the character of agriculture. Yet, working as the true agent or investigator of a group of good farmers they may become of great service to the country. We think the great majority of these young men desire to work as true agent or representative rather than to try to force their opinions upon practical men. We can see a dozen ways in which such a young man can be very useful to an organization of farmers. Such farmers could not, as individuals, spend the time to investigate problems, but the county agent can do it for them when they agree upon what they want. Thus this farm bureau will give the farmers a chance to have certain important work done which they could hardly do themselves. The safety of the farm bureau lies in self-help—the farmers themselves to control the movement and keep it free.

*

"THERE'S a shadow on the White House
Death's hand is at the door,
With a message that comes ever
Alike to rich and poor!"

It is one of the horrors of war that it drives the mind from its duty toward the living and the dead. The war news from Europe has so absorbed public attention that comparatively few of our people have fairly considered the fearful sorrow which has fallen upon President Wilson in the death of his wife. Mrs. Wilson was a gentle and unassuming woman, yet of strong character and influence. She was a home woman, absorbed in her efforts to be helpful to her husband and daughters. Few people knew that she was ill, but we may now realize the load of private care and grief which our President has carried silently and uncomplainingly through the hard public experiences of the past year. The warm, human heart of the nation goes out to President Wilson in these sad days with the earnest prayer that he may be sustained by a higher power in the tremendous tasks now before him.

*

DURING this frightful European war the policy of this nation should be one of strict and rigid neutrality. Every citizen should support the Administration in its efforts to avoid any official expression of sympathy for one side or the other. In a general way we all have our ideas as to the merits of the dispute, but not one in 10,000 can really understand what it is all about. The conditions in this country are such that most of us cannot comprehend the real feeling of the European people. Thus it would be the part of nonsense for this nation to enter any such controversy. Again, millions of our people came originally from Europe, and are tied by blood and by memory to the "Fatherland" or the "home land." We may respect their feelings, but they came here to make their home and help develop this nation on newer and more liberal lines. For this nation to adopt any policy except that of strict neutrality would be like mixing race hatreds together so as to form a political explosive. This nation should in this great struggle stand as the friend of peace and the world's great provider. In spite of all its horrors, this war will bring ultimate good to humanity. Who will say that the frightful slaughter of Napoleon's wars did not, in the end, give the masses of Europe a fairer chance? Before this war is over there will be less of autocratic, stern military government in the world. Some part of the loss and sorrow is sure to be felt in America, but if we can keep our heads and as a nation practice wisdom and self-restraint the future gain will be sure. We shall be in a position to secure the vast trade with South America which thus far we have failed to obtain. As a neutral nation, strong and honorable in its dealings with Europe, this nation will be expected, in time, to help settle terms of peace, finance the world's business and feed and provide for Europe's millions for years after the war closes. We have before us an unexampled period of national honor and prosperity which may be obtained through strict neutrality and fair dealing.

*

THE article by Mr. Ludwig calls attention to what we regard as one of the most important questions of soil culture. It is called "soil sanitation" for short. There seems to be no question that many of our grain soils are filled with the germs of plant diseases which reduce or injure the grain crop as seriously as potato scab, tomato blight or leaf-curl do the crops which they infest. We have become familiar with a disease like scab or blight and we recognize the folly of cultivating or fertilizing potatoes unless we are willing to soak the seed or spray the vines. Such treatment of the seed and the crop is as important as the use of fertilizers. More so in fact, for the plant afflicted with disease cannot make profitable use of its food. We believe that some if not many western soils have failed to give profitable yields of grain—not because they were "worn out" but because they were "sick"—that is, filled with germs of grain diseases. Applications of soluble fertilizers may give increased yields by stimulating the sick plants on such soils, but clean seed and sanitary treatment would double the effect of such fertilizers. This is one of the big, new problems which both our scientists and practical men must work out. A farmer would not knowingly feed good grain and hay to swine or cattle so sick that they could only make half a normal growth. Yet that is what he is doing when he puts sick seed into a sick soil.

*

ONE of our New York readers was induced to take out an insurance policy to cover accidents to a farm hand. Some of the insurance agents are trying to make farmers believe they are liable under the compensation law even when that law expressly exempts them. At any rate this farm hand was insured. He fell off a load of hay and was laid up for a few days. The insurance company was notified and sent the following:

We beg to acknowlege the receipt of your report of accident in the above case. The facts are as follows: "Lost control of horses going into barn with load of hay." Also injured's occupation is given as "farming."

Section 3 of the Workmen's Compensation Law, subdivision 4, which defines the meaning of the word "employee" ends with the following language: "and shall not include farm laborers or domestic servants." In view of this language of the law injured will not be entitled to any compensation. Should he, however, make a claim for such please notify us immediately. Also if any forms are sent you by the Commission to be filled out kindly send them to us, and we will instruct you in the matter. Likewise should the Commission serve any papers or subpoenaes upon you please mail them to us at this office at once. Kindly incur no expense on our account in connection with this case, except the doctor's bill which has already been incurred. Please do not pay this but send the bill to us.

Yours truly,
THE FIDELITY & CASUALTY CO.

To this the farmer made reply.

I have read your letter over carefully. It would seem to me if what you say is so, and you must know what you are talking about, I do not need any insurance. Please tell me briefly what I do get for my money.

You will see the point of all this. The farmer pays for the insurance, being told that he is liable in spite of the law's wording. The man is hurt, but the company now states that under the law the man is not "entitled to any compensation." The farmer has the experience, the hired man has the bruises and the insurance company has the money! Why did they take the farmer's money if they knew the law exempted him from liability?

*

GIVE us the power to make men and women *think* sanely and seriously about their problems, and we will make history. It is hard for the average man to think. It means hard work and dog-like concentration of mind, and it leads a man to a point where he must face the truth with moral courage or else go through life trying to make excuses to himself. Thus the majority of men are content with thinking that they think, while they actually wear the readymade thoughts of others much as they wear clothing. He is the greatest benefactor of the human race who can make his fellow man *think* liberally and broadly. He is the oppressor of his kind who substitutes prejudice, superstition or partisan hatred for thought, and makes weaker minds think it is the true article. The new word "scatter-mindedness" expresses the condition which prevents many from thinking. This trouble starts from childhood. In a discussion of what to do with our dull children, Prof. O'Shea of Wisconsin says:

One cause of dullness is due wholly to the way in which children are trained from the second or third year up to maturity. This is lack of mental concentration. No child can get along very well in the home or in the school unless he can keep his mind on the thing which is being said to him, or the task which has been assigned him, or the work he is trying to accomplish. If he is distracted by everything that is happening around him, he will be certain to fall behind in the school; and he will be a cause of annoyance in the home, because he cannot readily get the directions which are given him, and he cannot command his attention so as to do what is expected of him.

This habit of mental concentration is one of the most important essentials of success in any enterprise. Without it no man can think through a subject, and unless a man can do that the subject is master of the man.

BREVITIES.

A VERY interesting account of garbage-fed hogs and cholera on page 1038.

A DRESSING for sores on horses—one part standard carbolic acid and three parts sweet oil.

A PAINT for houses or nests where vermin abound—one part crude carbolic acid and three parts kerosene. Swab it on well.

No use waiting for the South American trade to be developed. Right in your own town people are sending 100 miles away for food which you can supply.

DR. CLINTON of Connecticut reports injury to leaves of Lima beans which could not be identified until it was traced to Paris green used with bran as a bait for cutworms.

THE Hope Farm man has had much sympathy and good advice as the outcome of his adventure with the heifer. Here is a sample: "Mighty glad heifer did you no harm; should not advise bull-fighting as an exercise for you. Try golf, it is more fashionable." What about hoeing strawberries?

THE WAR AND COMMERCE.

DEFINITE price advances have now been made in a large number of staple products. Flour is up $1.35 per barrel; wheat, 15 to 20 cents per bushel; corn, 15 cents (part of this rise being due to drought damage); sugar $1.60 per 100 pounds; beans, $1.50 to $2 per 100 pounds; coffee, two cents per pound; and tea, four cents. There is a general rise in the price of chemicals. Many of them come from Germany, and that source is entirely cut off. Others are used in explosives, for which there is increased demand. Carbolic acid is 25 cents per pound higher; benzoate of soda, 15 cents per pound; menthol, $1.50 per pound; saltpetre, two cents higher; and potash, used in glass making, 13 cents per pound advanced.

Domestic meats are all two to three cents per pound higher, partly owing to the alleged scarcity which the "meat trust" is continually harping on. It is difficult to understand how a two cent advance in price can increase the supply of meat, but that is the way it works with products that are kept in secret storage.

Our supply of Egyptian cotton, used in making high-grade yarns, is getting short; raw silk is scarce, and the same is true of some grades of foreign wool. Domestic cotton is low, because of the foreign demand being dead, and there has been practically no change in price of the home wool crop.

The war has as yet made no appreciable change in butter and egg prices at New York. Canada reports a higher market on both of these staples. Horses and mules suitable for war purposes are expected to advance heavily.

Great efforts are being made to move wheat to Europe. Ships for British and Belgian points are expected to renew sailings soon. Belgium has offered to insure wheat shipments sent there. German ports are closed and will doubtless remain so until the war ceases or Germany wins a naval victory decisive enough to make the North Sea and waters adjacent to the Atlantic safe for her merchant vessels. At present nearly 120 merchant vessels of commercial importance are tied up, among them the immense Hamburg-American and North German Lloyd lines. In the loss of revenue from all this shipping, and the stagnation of business in many lines, the industrial world is paying its allotment for the horrid luxury of war.

NEW JERSEY HORTICULTURAL MEETING.

ORCHARDSIDE, the home of Mr. and Mrs. John H. Barclay, was the goal for the members of the New Jersey State Horticultural Society and their friends from Pennsylvania and Maryland as well as New Jersey. The threatening weather of the early morning delayed, but did little else in hindering the getting together from all points in the State in one of the largest Summer meetings so far held. The farm was in its best trim, with barns filled to overflowing and grain in a score and more of well-made stacks, a fine field of potatoes waiting for the diggers to get busy, which all told of the successful work of the season. But to mention the Barclays always brings to mind the blue ribbon apples we have been seeing at Trenton, New Brunswick, Freehold, in our own State, to say nothing of the boxes sent to Rochester, Pittsburgh and other State meetings. To see the trees on which this fruit has been grown so successfully and to see the young orchards just showing what they will do in a few years was the great attraction, and the loaded mature trees, propped and thinned, well repaid the journey by rail, trolley, and auto.

President Hendrickson called on Mr. Barclay first, and he cordially welcomed the assembled guests and told them the farm was for inspection for their benefit, and that he was ready to explain all he could, that might need some explanation. As the promised speakers failed to arrive, Prof. Blake entered at once into a discussion of some of the leading peach questions of the hour, again emphasizing the importance of thinning the heavy crops of this year. Packing the carriers was then fully treated, and men were there to show how they should be filled. Winter injury is still with the peach growers, and some trees are going this Summer. The newer varieties were shown from the Vineland orchard, giving us a chance to see some of the widely advertised kinds that sometimes prove old friends under new names. After extending a cordial invitation for the next Winter meeting to be held in the new Agricultural building at New Brunswick, he told of the crowded condition of the Agricultural courses and needs of the young men of our State, who should be taught in New Jersey what they will need to practice here to be successful. He made an earnest appeal to the farmers present, to see that these wants are properly looked after.

Dr. Cook told of the rapid increase in the inquiries received by his department and the great number of complaints of diseases of farm crops; 135 complaints of different diseases were received last season. It shows that the work of the Experiment Station is being recognized by the farmers, and the necessity of having enough men at New Brunswick to investigate these diseases and learn how to combat them promptly.

In answer to numerous questions along his line, Dr. Headlee again told of the great efficiency of "Black Leaf 40" in fighting lice of various kinds. If properly used he thinks we need fear but little from these attacks. Keeping the trunks clean on our pear trees and using Black Leaf 40 at the proper times, he thinks will keep that great pest pear psylla in check. It looks now as if we would find a help against the peach borer in a soft grade of asphaltum that has shown no injury after being on the tested trees a year. There were many less borers where the tree trunks have been covered from early June till October, but the knife must still be used. For greenhouse work a stronger solution of nicotine has been found necessary and we are told that a leading nursery firm has kept the lice from their roses with one application of an extra strong nicotine solution. To overcome the bark beetle that injures the trees weakened by Winter injury, careful trimming out of all dead wood and keeping the trees vigorous as possible was advised. After lunch the crowds separated and were seen in all parts of the farm as well as enjoying the social opportunities, not the least valuable part of these Summer meetings, as we get better acquainted with our individual brothers, and perhaps can aid a fellow grower in solving some trouble. H. G. T.

EVENTS OF THE WEEK.

DOMESTIC.—William H. Cooper, the convicted head of the New York Central Realty Company, was sentenced by Judge Grubb in the United States District Court, August 7, to serve three years in Atlanta penitentiary for fraudulent use of the mails in the sale of about $500,000 of the bonds of his company. Cooper was indicted with Claude J. Van Slyke, James A. Robinson and Ernest Sharp. Van Slyke and Robinson pleaded guilty and turned Government witnesses.

New Jersey factories are beginning to feel the effects of the European war in their shortage of raw material. Hat factories in the Orange Valley get all their supplies from Europe, and are said to have only enough on hand to last through the Fall. Electrical works, pharmaceutical supplies, dyers, and textiles, including silks and towelings, are seriously affected.

Under the ordinance passed by the New York City Board of Aldermen June 23, all horse-watering troughs in the city have been closed. The Society for the Prevention of Cruelty to Animals is installing faucets so that drivers can fill their pails. Every commercial vehicle to which a horse is attached must now be provided with a pail, under penalty of fine or imprisonment. This order is due to the prevalence of glanders.

To reëstablish the salmon fishing industry on the New England coast, the Federal Bureau of Fisheries has begun the work of introducing the humpback salmon of the Pacific Coast into the littoral waters of Maine. This native salmon of New England has become very scarce, and, realizing the impossibility of ever reëstablishing the species, the Bureau has selected the humpback as a substitute. In 1913 the humpback run in Puget Sound was valued at $4,000,000.

Owing to the fear of German vessels being seized until peace had been restored in Europe, no more potash will be shipped to this country. The Kali Syndicate controls 53 potash mines in Germany, which furnish the potash to the world. Over one million tons of potash are shipped annually to the United States.

The Bank of England has made plans to send shipments of gold to Ottawa, Canada, to be deposited with the Treasurer-General to the bank's credit. The plan, in the opinion of persons best informed as to the situation, will cause a speedy reduction in the rate of exchange and resumption of commodity shipments to England. It will also cause the shipment to Canada of at least $5,000,000 of the $10,600,000 gold brought back by the Kronprinzessen Cecilie. Such a step will not only strengthen the reserves of England's great financial institution but will also tend to liquidate the enormous debts which this country now owes on the other side of the Atlantic, owing to the extensive security liquidation of the last few days of trading in the stock market and the swinging against this country of the balance of trade. Such a step will also reduce the exorbitant rates existing in foreign exchange, according to high authorities, and will undoubtedly open the way for shipments of American grain and other commodities to England at least, and perhaps France. The Bank of England can issue notes against a supply of gold placed to its credit in the vaults of the Treasurer-General at Ottawa just as well as it could against gold in its own vaults in London. Not only does the Bank propose to have gold from this country placed to its credit in Canada, but it has laid all plans for the establishment of another depositary in South Africa. This will further increase the reserves and actual gold supply of the Bank, in that it will have at its command all the gold it wishes from the gold mines of the Transvaal. The depositing of gold from this country in the vaults of the Canadian Government at Ottawa to the credit of the Bank of England is also considered as a strategic move on the part of that institution to prevent its having to assume war risks on the precious metal.

WASHINGTON.—Instructions to collectors of customs regarding foreign bound vessels were issued August 8 by the secretaries of the Treasury and Commerce, following a conference of department officials, the most important order bearing on the European war being to the effect that any vessel "whose character as a merchant vessel is established to your satisfaction is entitled to clearance, no matter what the character of her cargo or what her destination." Another order is that the collectors shall not refuse clearance to merchant vessels, whether of the United States or other neutral power, or whether of a belligerent power, "solely on the ground that the cargo contains contraband of war."

The Austrian ambassador has called the attention of the State Department to the inconvenience, loss and trouble which would result because of the interruption of direct mail shipping between the United States on the one hand and Austria and Germany on the other. If given to English lines, the Austrian Ambassador said, the mails to Austria and Germany would be held in England. The Postmaster-General replied that the Department had already issued orders that all mail going to Austria-Hungary and Germany, addressed via Rotterdam, be despatched by Dutch liners unless it could be more expeditiously sent by other liners. Since the declaration of war between Germany and Great Britain neither German nor Austro-Hungarian mail has been sent on British ships.

Two measures designed particularly to aid the cotton producers of the South in the emergency brought about by the European war were introduced in the Senate, August 11. One amended the banking and currency act so that emergency currency may be issued upon notes, drafts and bills of exchange, secured by staple agricultural products, having not more than four months to run. It provides that such securities shall be classed as "prime commercial paper" within the meaning of the act and that emergency currency may be issued against them to the extent of 75 per cent. of their face value. The other measure authorized the Secretary of the Treasury to withhold from the banks of nine cotton growing States—North Carolina, South Carolina, Georgia, Alabama, Mississippi, Louisiana, Texas, Oklahoma and Arkansas—50 per cent. of the emergency currency which could be issued to them. The Secretary of the Treasury is further authorized to advance upon notes secured by warehouse receipts for lint cotton in bales for a term not to exceed twelve months Treasury notes to an amount equal to 50 per cent. of the emergency currency to which the banks of these States were entitled under the law.

THE EUROPEAN WAR.—August 8 it was reported that Great Britain had seized German colonies in Africa, Port Lome on the Gold Coast, and South Togoland, where a high-power wireless station had been established. The German forces entered the town of Liege, Belgium, but the forts were still held by the Belgians. The German losses at Liege were very heavy, but reports as to number were contradictory, some going as high as 31,000, others 8,000 or less. British troops were landed at Calais August 9, and were reported, August 12, to be entrenched at Namur, Belgium. August 9-12 French troops were in contact with the Germans in Upper Alsace, but were checked in their invasion of that province. Very little was known as to British naval movements, but the Canadian Government announced August 11 that the North Atlantic was safe for Canadian shipping, and sailings were to be resumed without delay. August 11 the British Admiral announced that the North Sea was closed to merchant vessels; having being planted with contact mines by the Germans, the British intended to mine it further. No reports of the British naval forces were given out, except that the cruiser Amphion was destroyed with 136 men by a mine, after sinking the German mine-laying vessel Konigin Luise. Italy and Holland remain neutral; Portugal has announced herself as an ally of England. Both England and France announced war August 13 with Austria. It was announced August 12 that the Russian invasion of Austria had begun. It was reported that the Austrians had been driven out of Servia, but Servia and Montenegro had united against Bosnia, while Roumania was siding with Austria. It was believed August 12 that Japan was preparing to attack the German port at Tsing-tao, China. It was evident, August 12, that Holland feared German invasion, as a state of war was proclaimed in the provinces of Limburg, North Brabant, Zeeland and Gelderland.

HARVESTER TRUST DECISION.—The International Harvester Company was declared to be a monopoly in restraint of interstate and foreign trade, and was ordered dissolved by a majority decision in the United States District Court, August 12. Unless the $140,000,000 corporation submits a plan for the dissolution of the combination into at least three independent concerns within ninety days, or in case of appeal within ninety days of the issuance of an appeal mandate from the United States Supreme Court, the decision announces that the court will entertain an application for the appointment of a receiver for all the properties of the corporation. The decision of the court was given by Circuit Judge Walter I. Smith, of Iowa, with which Judge William C. Hook, of Kansas agreed, and from which Judge Walter A. Sanborn, of Minnesota dissented. The majority opinion held that the International Harvester Company was from its organization in 1902 in violation of the Sherman law. The original corporation, formed of five concerns, violated the first section of the Sherman act by restraining competition among themselves. The combined organization also tended to monopolize trade in contravention of the second section of this law. The decision declares that while the International Harvester Company and its selling organization, the International Harvester Company of America, control from 80 to 85 per cent. of the trade in agricultural implements manufactured by them, their treatment of smaller competitors in general has been fair and just. The court finds fault with the actions of the corporation, aside from the technical violation of the Sherman law, for only two actions. The opinion declares that there was no excuse for the advertising of the products of D. M. Osborne & Co. as independent for two years after it had virtually entered the International Harvester Company. This advertising was to induce purchasers, the court finds, from those who were opposed to buying from the combination. The other act censured by the decision was the manner in which the five original concerns were turned over to the International company by William C. Lane, a New York banker, who contended that he had purchased the properties.

GOVERNMENT CROP REPORT.

The growing condition of the various crops on August 1, expressed in percentages of their ten-year average (not the normal) on August 1.

Wheat	118.7
Apples	113.3
Lemons	105.4
Grapes	104.7
Raspberries	104.7
Barley	103.9
Kaffir corn	103.8
Sugar beets	103.4
Alfalfa	103.4
Hay (all)	103.3
Peaches	102.9
Oranges	102.2
Beans (drying)	101.8
Cantaloupes	101.2
Millet	100.8
Hops	100.0
Broom corn	100.0

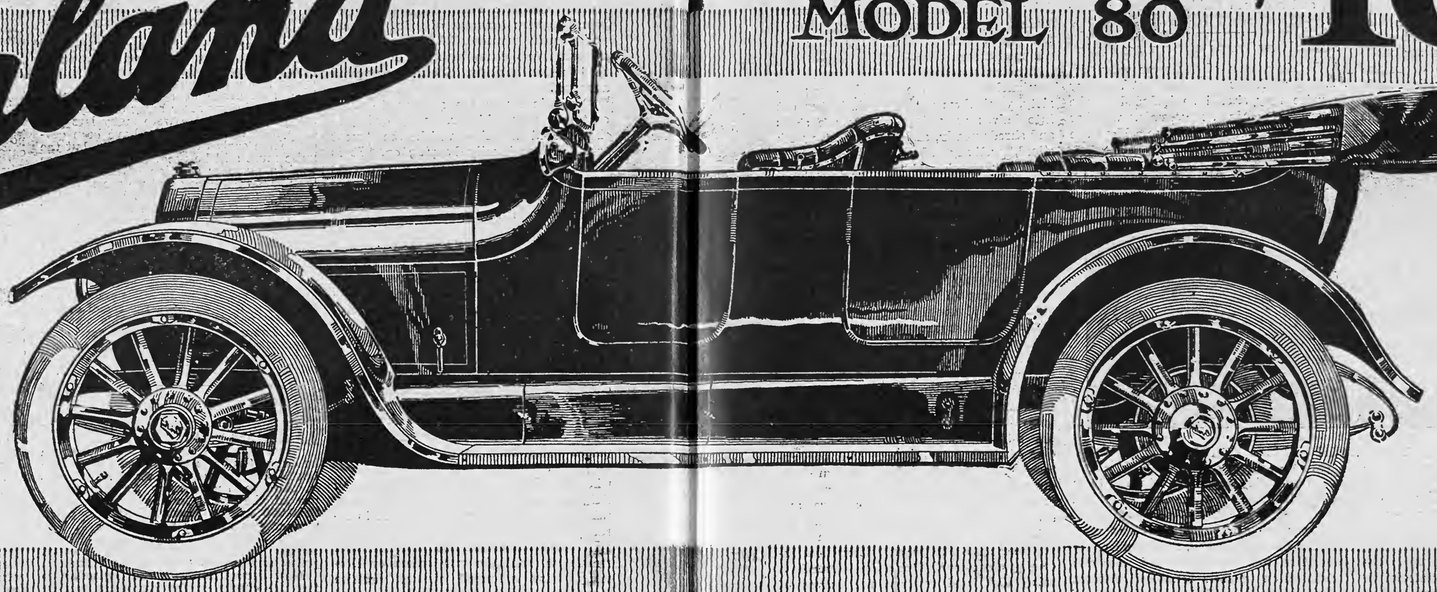
Overland

1915 MODEL 80 $1075



BY INVITATION MEMBER OF

This is the car selected by the Rice Leaders of the World Association as prizes for the leading salesmen of the world.

The Greatest Motor Car Value Ever Offered

WE have always given more car for less money than any other motor car manufacturer in the world.

We have always given a superior car, a more powerful car, a more practical car and the most economical car.

That is why more Overlands have been bought than any other similar type of car ever produced.

Now, with pride, we announce our latest car—Model 80—the greatest value this factory has ever placed on the market.

We wish particularly to call your attention to the fact that while this 1915 model has innumerable improvements, enlargements and refinements, *the price has not been advanced.*

This season we shall build 75,000 cars! This enormous increase in production again places us in the enviable and supreme position of being able to give still more value for still less money than any other manufacturer.

Following are the facts! Read each paragraph carefully!

Model 80 has a brand-new stream-line body. Its full sweeping stream-lines blend and harmonize perfectly with the balance of the symmetrical design. All visible lines are absolutely clean, unbroken and uninterrupted.

The new crowned moulded fenders, new rounded radiator, new hood slightly sloped, and flush U doors with disappearing hinges, contributing the additional touches of exterior grace and modishness which distinguish costly imported cars.

The new tonneau is much larger—both in width and in depth.

The new cushioned upholstery is also considerably deeper and softer.

This model is equipped with the finest electric starting and electric lighting system. All switches, in a compact switch box, are conveniently located on the steering column. Thus in the driving position, without stretching forward or bending down, you start the car, drive the car and control the electric horn and all head, side, tail, and dash lights.

This car has left-hand drive and center control.

The tires are larger this year, being 34 inch by 4 inch all around. These tires can be quickly detached from the rims which are demountable. One extra rim furnished.

Ignition is high tension magneto, independent of starting and lighting system. It requires no dry cells

Fundamentally the chassis remains as before. The front axle is larger; the wheels are larger; the frame is heavier and stouter; gears are made of 3½% nickel steel; there are integral grease cups in spring bolts; and other mechanical refinements which are described in detail in our new catalogue.

But otherwise in no possible way could we improve the splendid Overland chassis that is giving such satisfactory service to 50,000 nineteen fourteen owners.

This new Overland rides with remarkable smoothness, taking the ruts and rough spots with the ease of the highest priced cars.

There is the famous, powerful, speedy, snappy, economical and quiet 35 horsepower Overland motor; and a long wheelbase of 114 inches.

This car comes complete. Electric starter, electric lights, built-in windshield, mohair top and boot, extra rim, jeweled magnetic speedometer, electric horn, robe rail, foot rest and curtain box.

This new model is ready for your inspection in practically every city and town in the country.

Dealers are now taking orders. Make arrangements now for your demonstration.

A Few of the 1915 Model 80 Features

Motor 35 h. p.
New full stream-line body
Instrument board in cowl dash
Individual front seats, high backs
Tonneau, longer and wider
Upholstery, deeper and softer
Windshield, rain vision, ventilating type, built-in
Crowned fenders
Electric starter
Electric lights
High-tension ignition
Thermo-syphon cooling
Five-bearing crankshaft
Rear axle, floating type
Spring, rear, 3-4 eliptic, extra long, underslung
Wheel base, 114 inches
Larger tires, 34" x 4"
Demountable rims—one extra
Left-hand drive
Beautiful new Brewster green body finish
Complete equipment

Woman and the Home

From Day to Day

The Glory of War.

Hoof beat and trumpet blast
  And banners in the dawn!
And what of the grain in the fallow field
  When the husbandman has gone?

Sword song and battle roar,
  And the great grim fighting line!
And what of the woman in the door
  And the blown grape on the vine?

Drum beat and draped flag
  And he beneath his shield—
And what of the woman weeping low,
  And the dead grain in the field?

—Dana Burnet in the New York Sun.

*

CORRESPONDENTS sending inquiries to this department are requested, in all cases, to give full name and address. This will not be published but is required as a guarantee of good faith. It also enables us to reply by letter, where this seems advisable. We are often asked, by a hurried correspondent, to reply in the next issue of the paper, at a time when that issue is already on the press. Some questions, too, while of vital importance to the inquirer, are not of general interest, and we feel unable to print them, though very glad of an opportunity to answer by letter.

*

THE Children's Bureau of the Department of Labor has issued a bulletin on "Laws Relating to Mothers' Pensions in the United States, Denmark and New Zealand." From this we learn that Missouri was the first State to pass a law providing such pensions. In 1913, of the 42 State Legislatures then in session, 27 had before them bills providing for the support of dependent children in their own homes out of public funds. The bulletin includes a list of references on "mothers' pensions," which will be helpful to anyone making a study of this subject.

*

A RECIPE index file is much handier than a book for keeping one's collected recipes. Such a file consists of a well-finished little cabinet of oak or beech, containing 100 ruled cards, 5x5 inches, with 23 guide cards to classify the recipes. It is very easy to slip a card into its place, arranging alphabetically, and it is taken out, and may be pinned up, or otherwise conveniently arranged, while being consulted. We all know the bother of flattening out a bulky recipe book, and making it stay put, while we get together the materials needed. The recipe file described costs 80 cents.

*

HOURLY nursing service for persons who do not need to go to a hospital, but who require the skilled attention of a trained nurse, is to be established by the Nurses' Registry Association of this City. The charge is to be 75 cents an hour. There are many patients who cannot afford to pay a weekly salary to a trained nurse, yet who need skilled attention at intervals, and this service will be of enormous benefit to them. We think very often of the need for such skill in isolated country places, and we hope, some time, to learn of a rural nursing system, similar to the Australian Plunkitt nurses. Why could not some strong Grange send one of its own farm girls to a good nurses' training school, to return, after finishing the course of instruction, to take up this work in her home district?

Seen in New York Shops.

JOCKEY caps have appeared as a new mode in millinery. They are exactly like the real jockey's headgear, a round cap put together in sections, with a projecting visor; the only trimming is a flat button on top, and a ribbon band with a small bow at the back. Some are made entirely of black velvet, some are black and white striped satin with black satin visor, and others are of white serge. Some of them have soft draped balloon crowns. They are likely to be worn a good deal by those who like extreme models, but they give the wearer a sort of bold jauntiness that is not admirable. Prices of the caps run from $2.75 to $4.50.

Blouses of polka-dot lawn are pretty and new. They are made of fine lawn, with pink or blue dots, the sleeves being set in with hemstitched white lawn; the rolling collar and turn-back cuffs being of the white hemstitched lawn. Ready-made, they cost $3, but this is a style which might well be copied by the home dressmaker; there are few localities where polka-dot dawn is not obtainable.

Among little girls' dresses we see a greater tendency to do away with petticoats, and substitute bloomers of the same material as the dress. These bloomers are attached to a sleeveless underwaist. Some beautiful little frocks are made of homespun linen decorated with colored embroidery worked like the peasant embroidery of Roumania and other Balkan States. Such dresses are made like plain slips with kimono or raglan sleeves, the embroidery decorating neck, sleeves and hem.

Many new Fall skirts are of side pleating, attached to a deep yoke. These yokes are often outlined with braid and finished with buttons. Anyone who has saved a separate skirt in good preservation from the time when pleats were "in" can remodel it by cutting off the top, which used to be pleated right up to the belt, and using some of this material to form a plain yoke. Skirts are not as long as they have been; indeed, some of them are short enough to look rather awkward, according to recent standards.

Jet ear-rings are extremely popular, especially hoops and long pendants. Of course they are made with the screw loops that obviate the necessity for piercing the ears. A regular 1870 effect is given by long jet ear-rings where the wearer has her hair drawn high, a little flat hat perched on one side, and a long-waisted basque over a pleated skirt. Another old fashion revived is the wearing of a band of black velvet high up around the throat. Jet bangle bracelets and necklets are also much worn. The handsome cut jet is quite expensive, but there are many cheaper imitations.

Infants' diapers of soft absorbent paper cost 10 cents a dozen. They are placed inside the ordinary diaper.

Many white satin hats are seen in small close shapes. The new styles in hairdressing are very close to the head, the hair being drawn up to the top, hence new hats are quite small in the crown, though some new models are wider in the brim. The little white satin hats are trimmed entirely in white, many with wreaths of wheat. The wheat used in millinery, which comes in all sorts of colors unknown to normal cereals, is always of the bearded variety, and gives a very odd effect when the wreath is used to edge the brim, the wearer's face being surrounded by an aureole of bristles.

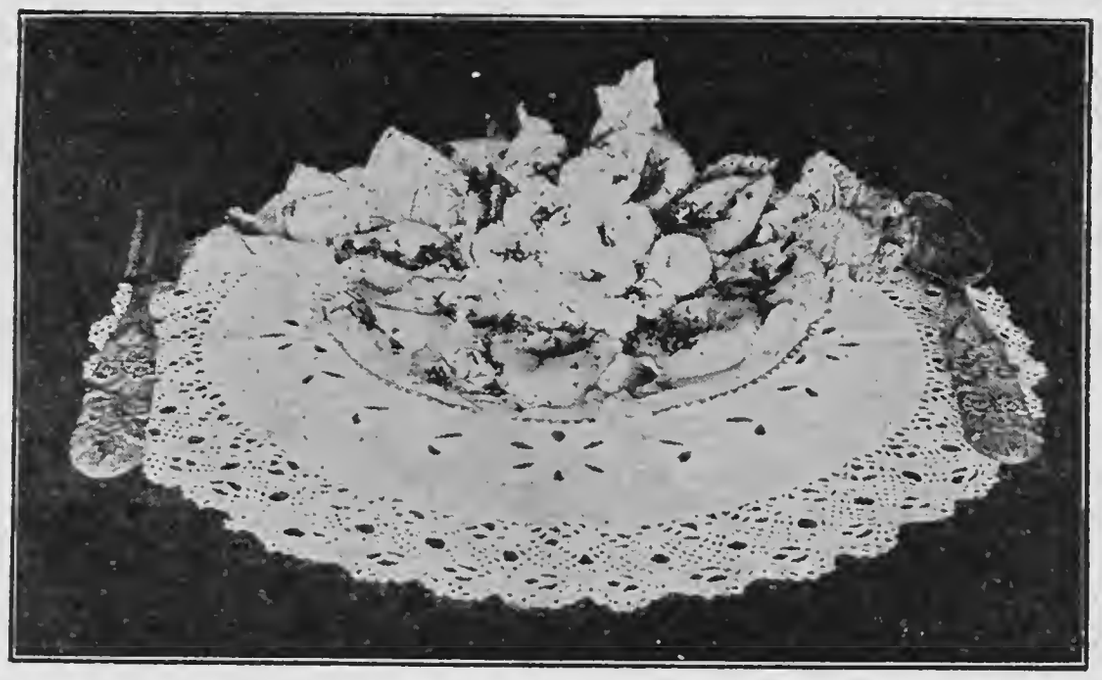
The vogue of the V-shaped neck continues, though some waists show square necks with odd flaring collars. The long popular "Dutch" neck is absolutely obsolete. The round collars of baby Irish worn two years ago would mark the wearer as old-fashioned, for baby Irish is obsolete too, but such things may be laid away carefully; "real" lace always has value, and these out of date shapes will all come in again. In the meantime, flaring collars of organdie cost next to nothing, and are both fashionable and becoming.

MUSKMELONS SERVED WITH SLICED PEACHES.

Some New Ways of Serving Fruit.

AT this season of the year when delicious fruits are abundant and low in price they should be included in the dietary as often as possible, whether eaten au naturel or otherwise. Here are some fascinating new ways of using them which will appeal to those tired of the old ones.

Grapes are always delightful no matter how they are served, and wonderfully decorative, too, when arranged with due consideration to their beautiful coloring. A tall glass dish filled with clusters of green and red ones, with a few of their silvery leaves and dainty tendrils falling over the edge, will rival the most elaborate of floral pieces as a table centrepiece, or, for a more simple picture of lusciousness heap a low basket of rough, brown bark high with Concords and Niagaras, and you will be charmed with the effect. Peaches, pears, plums, and apples, as well as the golden cantaloupe, have an ornamental value, either used along with their own green leaves, or when arranged with other fruit.



SALAD OF PEARS, CREAM CHEESE AND LETTUCE.

For a delicious dessert, nice to make while grapes are plentiful, extract the juice from three quarts of Concords, by first separating the skin from the pulp, and heating all slowly together until the juice begins to flow, and drain through cheesecloth. To the juice add an equal amount of water, the juice of two oranges, and one-half lemon, then strain again, and sweeten to taste. Soften two tablespoonfuls of gelatine in a little cold water, and dissolve, then stir it into the fruit mixture; turn into the freezer, and when partly frozen add one pint of well whipped cream, and continue freezing until firm.

Peach delight is a nice simple dessert suitable for a company luncheon, or at any time when a frozen sweet might be used. Bake a simple one egg cake in a thin sheet, or a stale sponge cake may be used. Cut the cake into squares or rounds; pour over each piece a little orange juice if you like, although this is not necessary. Pare and halve perfectly ripe peaches; remove the stones, and dispose one-half on each piece of cake; dust with powdered sugar, and surmount with a spoonful of sweetened whipped cream.

For a variation of this dish cut the cake into short, narrow strips, a little shorter than lady fingers. Line glass serving dishes with the strips of cake. Pare mellow peaches; stone, and mash them to a smooth pulp, then add a little lemon juice, and one-fourth cupful of crushed walnut meats; sweeten and chill. Fill the dishes with this, and top with the whipped cream.

Peaches are specially nice served with muskmelon. Use the small nutmeg variety, wash them well, and chill, then cut into halves crosswise; remove the seeds and shreds neatly, and fill the centre with sliced, well-sugared peaches. Even a plain cornstarch pudding will look elaborate, and taste delicious, if molded, then turned out on a pretty plate, and surrounded with whipped cream and halves of fresh peaches.

For an excellent peach ice cream, easily made, crush the fruit, and to each cup of the pulp add one-half cup of sugar, and one cup of thin cream, and freeze stiff. Or, if one likes the fruit frozen without the cream, add the unbeaten whites of six eggs to each quart of pulp, and freeze. This is exquisite served in the muskmelons with whipped cream.

Pears are usually considered only fit for canning and pickling, yet there are many pleasing ways of utilizing them for the table outside the preserving kettle. One of these is in the form of a particularly pretty salad. Wipe and pare medium-sized Bartlett pears and cut into halves lengthwise; remove the core, and drop each piece when finished into ice cold water to which a little lemon juice has been added, to prevent them from becoming discolored. Put crisp lettuce in a salad dish, and arrange the halves of fruit around the edge. Have ready some fresh cream cheese, seasoned and moistened with a little French salad dressing, made up into tiny balls, about the size of a walnut, pile these in the centre, and sprinkle them over with a little very finely chopped parsley, then moisten the whole with the simple dressing of oil and vinegar.

Pear fritters make a nice luncheon or supper dish, to make them, pare not too ripe pears, cut into halves and core. Make a batter of one cup of flour, two teaspoonfuls of baking powder, a speck of salt, one tablespoonful of sugar, and one-half cup of milk, and the beaten white of an egg. Dip each piece of pear in this, and fry in deep, hot fat. Drain on a napkin, or a piece of soft paper, and sprinkle with a little powdered sugar. Reserve the stems of the pears, and insert one in the pointed end of each fritter.

Pears are delicious baked. For this the small old-fashioned Seckels are best; wipe them, and put into a granite baking dish, pour a little molasses over them, and add one cup of boiling water; cover closely, and bake until tender. Serve either warm or cold.

ROSAMOND LAMPMAN.

Hominy Croquettes, With Cheese Sauce.—This is savory and nourishing for a meal served without meat. Mix three cupfuls of boiled hominy with two eggs, form into croquettes and fry a golden brown. Serve with this sauce: Put four tablespoonfuls of butter in a saucepan, and when melted, make smooth with three tablespoonfuls of flour; add a dash of paprika, salt and celery salt, and cook slowly while adding half a cupful of milk. When this has boiled for three minutes turn in a cupful of grated cheese.

Marlboro Pie.—Into two cupfuls of stewed and sifted apple sauce stir, while still hot, two tablespoonfuls of butter. Beat the yolks of two eggs, add one cupful of sugar, the juice of one lemon and the grated rind, a pinch of salt and half a cupful of fine cracker crumbs. Mix thoroughly and turn into a plate lined and bordered with rich pastry. Bake, and when done whip the whites of three eggs, four tablespoonfuls of sugar and half a tablespoonful of chopped candied orange peel. Pile it lightly over the pie and serve very cold.

A Wise Woman Says:

"THERE are some mighty queer things in human nature," said Mrs. Sage, after spending a busy morning working and thinking. "The people who are most determined to boss aren't always most capable of directing others. Yet they do most of the planning and deciding in this world. Others give way to them because there is no living with them on any other terms. A natural boss will say things have got to be so and so, and by sheer force of will bring it to pass. It may be good or bad in result, but it is accomplished, and others have to stand back and say it is excellent and couldn't be beat or there's no comfortable existence with the boss. And it is usually better than nothing, and the long-suffering ones can usually take it and make very comfortable shift to accept it as the best thing possible. Nothing of man's make is perfect, and in a year or so some other idea will sprout in the mind of the boss, and perhaps the whole thing may be made over, or tossed in the junk heap. Then the meek ones will say, 'What a wonderful mind for planning! What ability!'

"Yes. I know that I have admitted there is nothing of human arrangement that is perfect, but there are good things and poor things. And the meek person is more likely to have good ideas than the bossy one is, in many cases. Why, I have seen a quiet, unassuming man who could lay out the day's work for hired people, week in and week out, and make nearly every hour tell and nothing much neglected. And I have seen the man who bossed him not able to direct a piece of work so that the teams would not stand idle half the time, or the men soldier around filling in time with pretense at work because there was nowhere to take hold.

"Yet I own that the bossy man was after all the one who made the money and the meek one worked at day's wages. Left to himself the meek man dreaded responsibility. Knowing how much depended upon right management he could not sleep nights if burdened with the whole weight of care. He knew how, but he knew too much. He saw too clearly the outcome of bad planning, and faulty work. He had not the dash and daring that could say: 'Oh, hang the mistakes! If this doesn't go right we'll try some other way. If the men buck and aren't respectful, pitch them out and hire others. Right or wrong the thing has got to go now. Later we'll count the costs. Try another plan next time if this one doesn't make good.'

"Perhaps once in a while, nature puts both sorts of ability into one person, and the result is a captain of industry. But I suspect that more people succeed because able to select and keep efficient helpers than because fitted with extraordinary powers in several directions. It takes a certain share of generosity and forbearance on the part of the boss to get and keep a useful subordinate. Even the woman who keeps kitchen help knows that. In fact the meek people and the bossy ones need each other, but they don't always know it. The relatious of the meek ones very seldom know it. They say, 'But my son (or mayhe it is my husband) does all the work. His boss couldn't keep on a year if left to himself. Yet he takes all the profit, all the credit, all the leisure and all the satisfaction. It makes me mad, and I can't help it.'

"No, she can't help it, the woman who loves the meek man. Margaret Fuller told some great man of letters that she had become reconciled to the universe. We will skip his funny remark and advise all women to become reconciled to the universe. They can't alter human nature, but they can count their mercies. Often one they do not consider is that they do not have to live with the boss they are so tempted to hate. They love the meek man and feel tender of him for the very qualities that make him a contrast to his boss. They wouldn't have him different in any of his endearing qualities, but they would have him gentle and compassionate and patient at home, and a lion for boldness toward other men and the world's affairs.

"Here and there one sees a pair of brothers, a boss and a meek one, and they get on most successfully in business. They accumulate money, if they share equally. If one works for wages, the other has a growing bank account. Usually such a pair of brothers must have remarkable wives. At least the wife of the meek one must have unusual self-control and sagacity. If there are children in both households and the partnership goes on peacefully there is a miracle somewhere, very great generosity and forbearance in both households. For one discontented wife will upset even the most prosperous business arrangement.

"How queer we all are. Or rather, as the old Quaker said, 'Every one except thee and me is queer, and sometimes wife, I think thee is a little queer.'"

A. T. S.

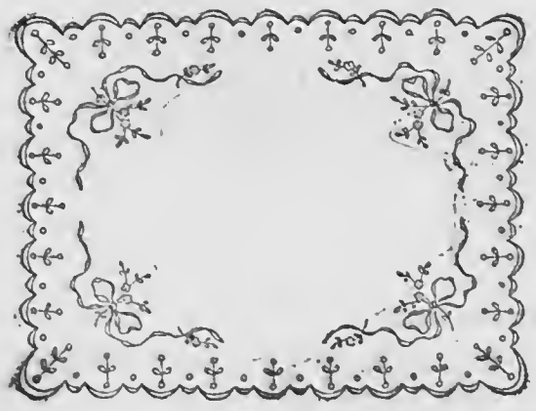
The Rural Patterns.

When ordering always give number and size of patterns desired. Price of each pattern 10 cents.

8185 Middy blouse for misses and small women. Cut in sizes 16 and 18 years. size 16 requires 2⅝ yards of 36 or 44-inch material with two yards 27-inch for trimming. 8310 Plain blouse.

Cut in sizes 34 to 42 bust measure. Size 38 requires 2⅜ yards of 36-inch material. 7907 Semi-princesse dress for misses and small women. Cut in sizes 16 and 18 years. Size 16 requires 3¾ yards of 36-inch material. 8174 Seven-gored skirt. Cut in sizes 26 to 36 waist measure. Size 30 requires 5 yards of 27 or 36-inch material if it has figure or nap, or 3¼ yards of 36-inch material which has neither figure or nap. 8203 Two-piece skirt. Cut in sizes 22 to 30 waist measure. Size 26 requires 2⅝ yards of 27 or 44-inch material with 3 yards 27-inch for long tunic.

No. 778. A design for embroidering an infant's pillow. The scalloped edges are to be padded and button-holed. The dots and ovals within the scallops can be



worked either solidly or as eyelets; the ribbon, flowers and leaves are to be worked solidly and the stems are to be outlined. Stamped on 21x16 white pure Irish linen, with mercerized floss to work, 60 cents.

Two Good Relishes.

TOMATO RELISH.—12 large tomatoes (green); four onions; six peppers, green and red; small cup of salt. Let stand over night, drain. Then add two bunches of celery, chopped; one-half cup sugar; one pint vinegar; spices to taste.

CUCUMBER RELISH.—One quart sliced cucumbers; one onion sliced fine; one green pepper; sprinkle with salt, let stand three hours, drain well and add one cup sugar; one teaspoonful white mustard seed; a little pepper, 20 cloves. Add vinegar to cover, scald, not boil, put in cans and seal. MRS. A. R.

The Front Porch Philosopher.

MY "front-porch philosopher" comes to me every Summer, pays her board, praises my efforts, brings me breezes from the big world where she works and travels, and leaves behind her some inspiration and much advice. At other seasons of the year she is a professor of household arts in one of our big universities. She has won me over to an oil range, simpler wall decorations and floor coverings; she has shown me how to fill my emergency cupboard, and many other helpful things; but just when I think she has a really intimate understanding of things, she disappoints me. Last Summer she came to me quite excitedly. She had been making a study of my kitchen, of its inconveniences, and how to remedy them. She had plans on paper for remodeling it at an expense of $75 (Oh, that $75!). In order to follow out her plans, to have the water-back of the stove nearer the pantry, she had deliberately moved the range, without thought of the chimney! Gas-stove theories.

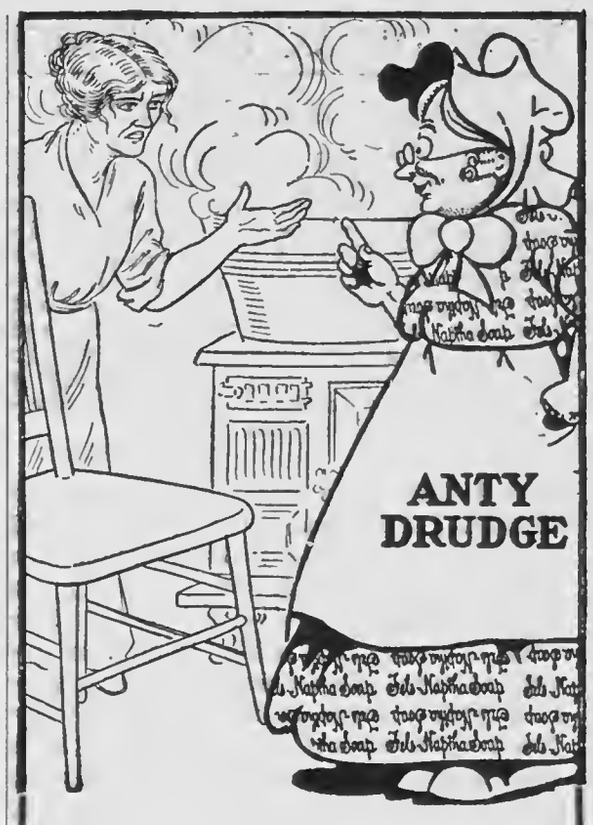
While she was here, I thought I would ask a mutual friend, a professional man and his wife, to a Sunday supper with us. I asked her for some suggestions for my menu. She was in her glory. She wrote it all down—a menu for an elaborate course dinner. There was work enough on it for two women a whole day. And I had said a Sunday night supper, and myself the only woman. At first I felt some resentment, and thought that I should tell her that I knew what a course dinner was, and what a farmhouse supper was, and of some of the simple, delightful meals which my friends and myself had exchanged. But I refrained. My friend meant well. No doubt she could have prepared that meal beautifully, without even soiling her white linen, but she would not have expected to gather all the vegetables required, tend the chickens from the cradle to the grave, fix the help's table, see that the children were still presentable, meanwhile cooking and then serving the meal.

I do not resent her possession of my cool porch. She may as well enjoy it; for the time I spend there is scarcely sufficient excuse for its existence. She knows it. She says she had always envied farm women their porch spaces and shady nooks; now she knows how little they count in a farm woman's life. (Isn't it a pity that she has measured us right in this respect?) It is her business to take pad and pencil, and outline plans to make it possible for us to find more time for those porch chairs. I grant that she and her kind have jarred us up somewhat and I do think we are moving forward a little.

I do not disapprove of courses in household arts; I should like to take one myself. But women of her type fill many columns in domestic papers, and farm women can always detect the lack of familiarity with their needs. We want more farm women to take such domestic courses, and write for us. They will find us responsive. L. S.

TOMATOES STUFFED WITH CORN.—Here is another recipe which I think is deserving of a place among those delicious recipes you printed two weeks ago for tomatoes, as it is a universal favorite with everybody who comes to the house. Scoop out the centers of round, smooth tomatoes and fill the cavities with corn cut from cob, same having been previously cooked. The corn is put through the fine knife of the meat grinder, and a little sugar, pepper and salt added. A teaspoon of melted butter is poured on the top of each tomato just before putting in the oven. Bake in a hot oven 15 minutes, or until tomatoes are soft. F. B.

Concord Cream.—Mix one pint of cream, one and a quarter cupfuls of grape juice and one-third cupful of sugar. Add lemon or fresh lime juice until palatably acid. Freeze, and serve in glasses. Garnish each glass with a tablespoonful of sweetened heavy cream beaten until stiff, and delicately flavored with vanilla. Sprinkle the top of cream with a pinch of pistachio nuts, finely chopped.



Mrs. Peevish—"I declare, I'm ashamed to ask you into this smelly place, Anty Drudge, but you know how it is on washday, with boiling clothes filling the room with steam. I'm just sick with the odor, and I'm about ready to give up."

Anty Drudge—"I think it's time you *did* give up your old-fashioned notions. Nobody up to date boils their clothes these days. They use Fels-Naptha Soap in cool or lukewarm water. There's no chance for disagreeable smell then. The only smell to Fels-Naptha is *clean* smell."

When you wash with Fels-Naptha Soap and cool or lukewarm water, you don't breathe in sudsy steam, nor fill your house with the smell of boiling clothes—and you get your work done easier, better and in half the time than ever before.

Fels-Naptha dissolves grease and makes dirt and stains vanish. It's just as good for all kinds of housework as it is for washing clothes.

Buy it by the box or carton and follow the easy directions on the Red and Green Wrapper.

Fels & Co., Philadelphia.

FELS-NAPTHA

Live Stock and Dairy

GARBAGE-FED HOGS AND CHOLERA.

NOTE that the mule-foot hog is not immune to cholera. This is a disease that science seems to have made little headway against. Has no one developed a resistant type of hog? Have experiments been made in sour-milk feeding? Sour milk is so effective against bacillary white diarrhœa in hens and against intestinal infection generally in the lower animals and in man, that it would seem as though it might be effective against the cholera bacillus.

A. COCHRAN.

Mule-foot hogs are not immune to cholera. This has been demonstrated time and again, and it is ridiculous for any one to advertise mule-foot hogs as immune from hog cholera unless they have been simultaneously treated or recovered from the disease. The only animals that I know of that are seemingly immune to cholera are those that have been treated with the double treatment, namely virus and serum simultaneously, and in addition those that we term "garbage-fed hogs," that is, animals that have been fed extensively on garbage refuse from cities and kept continuously under such conditions for a considerable length of time. This condition of garbage-fed pigs exists in certain localities, and the only way that we can account for this immunity is by assuming that in the garbage they have been fed scraps from pork products that have contained the cholera bacillus. This fact suggests that there is a possibility of getting animals naturally immune to the disease.

It is interesting to note that in sections around Barren Island they have endeavored to bring in breeding animals from outside of the district, but in every case they have succumbed to the disease, while natives not subjected to any serum treatment whatsoever apparently thrive, and show wonderful vitality. In fact at one of the large serum plants it is stated that when garbage-fed pigs are used for the production of serum, and injected with large amounts of virus without any protective serum whatsoever, very seldom is a loss reported.

Research and investigation during the past three or four years relating to hog cholera has put forward the serum treatment as well as the simultaneous treatment, the former establishing immunity only for a short period, and the latter in case reactions are secured, immunizes permanently, or for life. It would seem that effort should be directed toward establishing immunity by increasing the resistance of the animals, and to this end it is my judgment that in the future larger amounts of serum may be used, and smaller amounts of virus, which would result in greater security to the swine grower. The use of the serum and virus is past the experimental stage, and is extensively used in the Western States. It must be admitted, however, that hog cholera has been introduced into herds by means of using virus in case the serum accompanied its use did not protect, and to this end government regulation as well as State supervision has had the effect of putting the serum manufacturers on a more careful basis. In any event the serum must protect or havoc will prevail where the virus is used. It is claimed that in some cases hogs treated simultaneously are carriers or distributors of the disease. This is not probable unless the animals actually contract the disease or show an unusual re-action following injection.

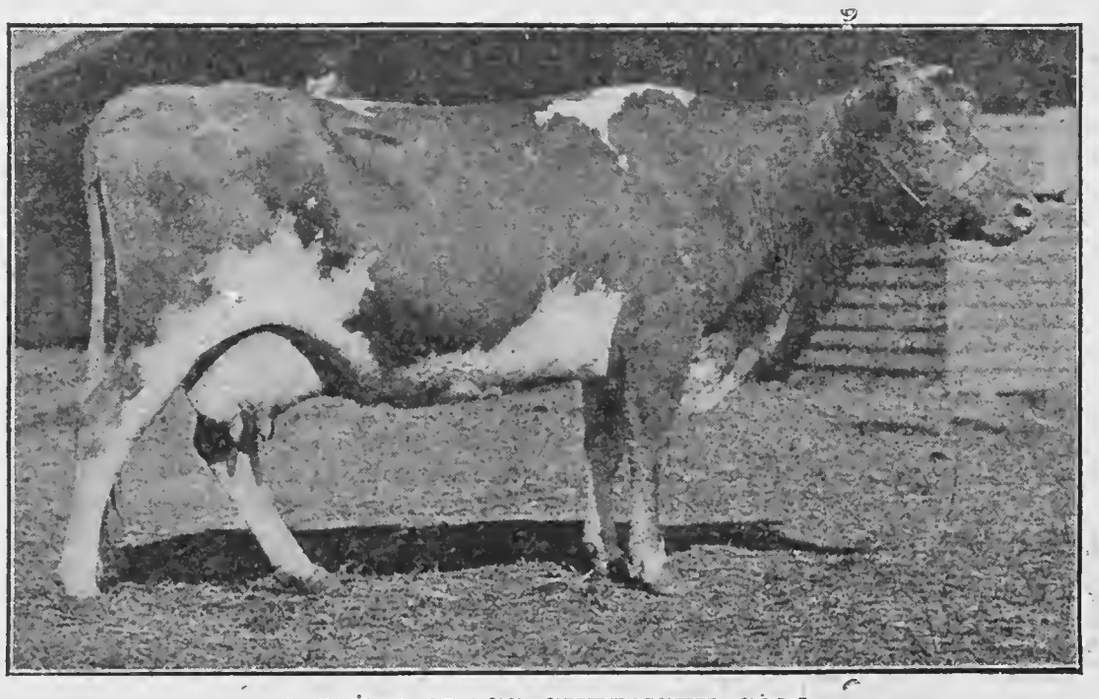
F. C. MINKLER.

A DAIRYMAN ON MILK PRICES.

The 35-cent Dollar.

IN a recent issue of THE R. N.-Y., F. D. H. writes that the past year has been a record-breaker for shipping dairy cattle out of the State, and I want to state that dairy cows will go out faster even in the future than in the past, unless there is a decided change in conditions, especially price. As a Madison Co., N. Y., dairy farmer, milking 50 cows the year around, I feel that I am in a position to state with authority that from a market milk standpoint, there is nothing in it.

Our cows are a heavy milking strain of purebred Holsteins, producing from 10,000 to 14,000 pounds of milk among the mature animals, and we figure, considering the price of feed and labor also, the price of milk to pay expenses only, but get our profit in sale of stock. There are about three months in the year when there is a profit in milk, these being January, February and June. January and February the price is usually 4¼ or 4½ cents per quart, which is somewhat reasonable for grain-feeding months, but why in the name of common sense the price then begins to decrease is more than I was ever able to figure out, as there is no surplus to any great extent in New York City, dealers, jobbers and retailers receive the same price from consumers as in January and February, and it also costs as much to produce milk as in those months. Still we have to take as low as 2⅞ cents in April, which is an actual loss of about one cent per quart. What is the result? I'll tell you the result, dairymen sell some of their stock to pay their November, December, March and



A HIGH CLASS GUERNSEY COW.

April feed bills. This is being done in Madison County by dairymen considered to be up-to-date and practical.

A good sensible price of milk to the producer is 4½ cents per quart in November, December, January, February, March and April, and 3½ cents the remaining months of the year. If a respectable price is not forthcoming I can conscientiously say that in a few years the consumer will pay considerably more for milk than at present, caused by the dealer giving no incentive to the farmer to produce milk. I do not blame the middleman nor the retailer in particular, but I do blame the whole system, i.e., I don't think the entire responsibility of price-fixing should rest in the hands of the middleman, a condition which now exists. If prices are to be *fixed* months ahead a reliable honest commission should do it, composed of two producers, two dealers and one disinterested person who is a good mathematician to figure out a price that will be of mutual benefit to all and not have such a one-sided affair. Right here I want to ask a question: Is the price of milk controlled by competition and supply and demand, when the price is fixed six months ahead by a large corporation fast becoming a monopoly? Perhaps some of our trust experts can answer this satisfactorily.

I heard from good authority not long ago that one milk dealer who controls only one station, paying Borden prices, cleaned up over $15,000 last year from 52 milk station patrons, or more than the combined net earnings of the dairymen.

Now let's figure here: The patrons will average an investment of at least $5,000 each, which totals $260,000, which means an income of 5.7%, taking it for granted that the dairymen total a net income of $15,000. This dealer, I happen to know, does not have an investment of $7,500 in horses, cans, etc., but to make figuring less confusing we will call it that amount, which shows that his investment netted him 200% last year. Is it any wonder that a large milk concern paid a dividend recently of something like 50%, besides putting 20 millions in new business? Of course I was told that milk dealers had bad debts, sour milk, etc., but don't dairymen also have losses in the way of cattle diseases, dried-up pastures, crop failures, etc.?

The Dairymen's League, properly handled will remedy the situation in time, but it is too bad that in a Christian nation one part of a business is forced to band together to fight the other part in order to get its just dues, instead of all hands getting together and figuring the thing out, each taking a good livable income and living in peace with each other and the world.

Madison Co., N. Y.

AILING ANIMALS.

Fleas on Cat.

WILL you tell me what we can do to kill fleas on a cat? A. R.

New York.

Put some Dalmatian insect powder into a gunny sack, then insert the cat, leaving its head outside, hold the mouth of the sack around the cat's neck and shake to get the powder among the hair of the animal. Repeat the treatment as often as found necessary. A. S. A.

Abnormal Breathing.

I HAVE a bay horse six years old that was very sick when he was brought here from the West two years ago. Since that time he has breathed quite hard, especially when being driven or hauling a heavy load. The trouble seems to be in his nose or nasal passage as he blows his nose frequently although there is no discharge from it. Would you advise using Fowler's solution? If so when and how much? O. S.

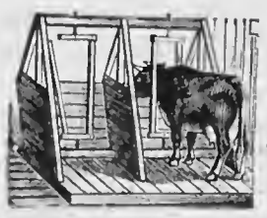
Give the solution if the horse is in thin condition. The difficulty in breathing probably is due to the pressure of a polypus (tumor) in nostril. If so the growth could be removed by a skilled surgeon. A. S. A.

Suspected Heaves.

A mare recently purchased seems to have a touch of the heaves now. When she works there seems to be a little too much of a movement in her flanks; she is a little nervous and has an occasional coughing spell. I know of several things that are said to be good to relieve heaves in old horses, and I also know what A. S. A. usually recommends, Fowler's solution, damp feed and other good care. It seems to me there ought to be something better than Fowler's solution. I know there are lots of horses working that have the heaves badly; some are using Fowler's solution, and I also know that the ones who are having the best results are using something else. F. T. S.

Pennsylvania.

We have no way of making sure that heaves is present in this case, and if it were we should prescribe Fowler's solution, as it is quite effective, one of the best remedies known for the disease and comparatively safe, while other remedies, such as lobelia, digitalis, stramonium, chloral, etc., are too dangerous to prescribe through a paper for general use by laymen. We cannot do better than advise you to treat the mare as if heaves were known to be present; for the feeding and management we prescribe are far more important in every case that the use of drugs. If our correspondent has any objection to the use of Fowler's solution, let him use proprietary heaves powders, such as his other friends no doubt are using. They temporarily allay heaves. A. S. A.



ROBERTSON'S CHAIN HANGING STANCHIONS

LOUDEN
BIRD PROOF BARN DOOR HANGER

This barn door hanger is not only bird-proof but proof against troubles of every kind. The enclosed track, made of one solid piece of high-grade steel pressed into tubular shape, prevents all obstruction, winter and summer. The sparrow is banished; snow, ice, rain or trash can never interfere with its smooth operation.
Center-hung on Roller-Bearing Tandem Trolleys makes Louden hung doors easy to move; flexible construction prevents breakage by crowding stock—always holds door close to the wall. Carries the heaviest doors without sagging.
Illustrated Catalog on Louden Barn Door Hangers, Steel Stalls and Stanchions, Feed and Litter Carriers, Hay Tools, Power Hoists, and other Louden Barn Equipment sent on request. See your local dealer or write us direct.
Let us help you plan your new barn. Our barn building experts are at your service. Suggestions and preliminary sketches FREE.

Decrease in Butter Fat.

THE man at the creamery where I take my milk says cows do not test as high in butterfat when they are shedding their hair. Is that so? When a cow is giving 40 pounds a day and is milked six months and drops to 20 pounds a day will it test more? I do not get any more when the cows drop; I always thought it would test more. P. S.
Pennsburg, Pa.

It is common experience among dairymen to have the butterfat content of the milk decrease during the season of the year when the cows are shedding their coats; especially is this true where animals are maintained under farm conditions and not regularly groomed nor fed with a liberal grain ration. This factor is a negative one, however, where the animals are more carefully cared for, and where their coats are kept in a sleek condition during the entire season.

There should be a slight difference in the test of the cow's milk referred to, when comparison is made with the period of her lactation when she is giving 40 pounds of milk per day with a period six months later when she is giving only 20 pounds per day. With some breeds it would be as much as 1%, and possibly more, but this would further depend upon the physical condition of the cow, and the amount of flesh that she was carrying when she freshened. If she was in extremely good health and carried considerable flesh, her test would be undoubtedly high, and if she was milked down and would lose this flesh six months later, it might be possible that the milk would not show a greater percentage of butterfat. With the average herd, however, there should be noted a difference, even though with cows in the herd freshening from time it is doubtful whether the variation would amount to much. F. C. M.

Trespassing Bulls.

WILL you tell me the law of New Jersey regarding bulls running at pasture or at large? I rented pasture last Summer for yearling heifers with the understanding that they would not accept any bulls for pasture. One neighbor had a scrub bull adjoining pasture. I asked him twice to keep up the bull, or keep him out of the pasture which he refused to do. Two of the heifers are with calf by his being in the pasture with them and will freshen this Spring. What damage can we get? M. S.
New Jersey.

As far as I can determine the only course to pursue in this instance is to sue the owner of the animal for trespass. The general law respecting trespassing by such animals is to be found in pamphlet law 1883, page 82, and pamphlet laws 1877, page 413, relating to animals breaking through fences. Of course, those laws confine the penalties therein imposed to where fences, known as lawful fences have been broken down. If the identity of the bull doing such damage could be definitely established, it would be an easy matter to establish the difference in value between a scrub and one sired by a purebred male, and it would seem that in any court of justice the difference in this amount could be recovered in case damage was claimed for trespass. F. C. M.

Contagious Abortion.

I LATELY had two cows that lost their calves by abortion. Carried calf about seven to eight months. I want method of treatment and care so they may breed again after disease may be cured. Is this disease spread by the bull? If so, should I get a veterinarian to examine the bull? The disease seems very prevalent in this vicinity. E. H.
Glenarm, Md.

If abortion becomes epidemic in a herd there is reason to suspect that it is due to a contagious infection and if the services of a trained veterinarian can be secured to direct treatment this would better be done. The treatment of contagious abortion is largely that of disinfection of animals, using a one to two per cent. solution of carbolic acid in water or some other standard disinfectant in proper strength. The stables should also be disinfected if cows are kept in them. Carbolic acid administered internally and methylene blue given in the food have both been strongly advocated as remedies for contagious abortion, though neither seems as yet to have gained the full confidence of the veterinary profession. Bulletin No. 90 from the Montana Station at Bozeman, Mont., describes the carbolic acid treatment and Bulletin 74 from the Vermont Station at Burlington, Vt., that with methylene blue. These may be obtained and their directions followed if you wish to treat your cattle yourself, but in most cases it would be better to secure the services of a graduate veterinarian. A bull may carry the infection from one cow to another and must be included in the treatment. M. B. D.

Mapes on the Poultry Meeting.

TOM BARRON has come and gone, and the Connecticut Poultry Association has held an epoch-making meeting, the occasion being the annual midsummer gathering at Storrs Agricultural College. The attendance was all that could be desired, taxing the college to its limit to provide accommodations for the crowd. The secretary, George V. Smith, handled the crowd with his usual dexterity, and to him belongs much of the credit for the success of the meeting. Most of the prominent poultrymen of the East were on hand, some motoring 500 miles or more in order to be there.

Mr. Barron who captured first place in the egg-laying contest last year, and who is still holding first place in the contesting pens this year, was the magnet. Pen 42, the sour milk pen belonging to Storrs, was one or two eggs ahead of him most of the time during the meeting, but this pen is not competing. Mr. Barron captured the crowd at the outset and held it to the last. Keen, good-natured, jolly and gentlemanly he met those Yankees half way every time. The climax was probably reached when he was induced to mount the roof of one of the pens on the contest grounds where the vast crowd could see him, handle a pen of birds he had never seen before, and try to pick out the best layer, just as cows are sometimes scored by points. He met this test three times, with R. I. Reds, with White Wyandottes, and with White Leghorns. While he did not succeed every time in picking the hen with the very highest score he came so near to it that everybody seemed satisfied, in view of the fact that he had no chance to see them on the ground in a natural position.

Before the meeting was over the utility men and the exhibition men, having come to the meeting in fear of a clash, found out seemingly, as far as I could judge, that their interests run so nearly in parallel lines that it is going to be easy to bind them together with the cords of brotherly love. From what I could learn on the ground I believe that some pens of the finest exhibition birds will be entered in the contest next year in an effort to prove that high-scoring birds are not necessarily poor layers, while utility breeders will try to pick good layers having the nearest possible resemblance to standard requirements.

My own impression is that we have something to learn from such English breeders as Mr. Barron, while possibly he has just as much to learn from America. The main points as I see them, in which he is ahead of us is that he has been studying his birds as individuals for 25 years, trap-nesting and selecting with reference to laying rather than standard requirements, and using skim-milk largely in the rations for both laying hens and young birds. He keeps about 7,000 head of poultry and 10 milking cows on a 20-acre farm. In addition to these he keeps two horses and a few young cattle, generally having some surplus hay to sell each year. It is a coincidence that while I have been advocating a combination of cows and poultry for the past three years, it remained for this man from England to clinch the lesson home by telling us that he has been putting the combination in practice so successfully for the past 20 years. He churns the cream into butter and feeds the skim-milk to the hens. In my opinion he is behind his American brothers in that he still sticks to the wet mash, and the small units both of chicks and laying hens. He admits that "my birds seem to do pretty well in America" where they are fed on dry mash.

PRICE, $75 to $100.00 EACH
All large, well bred, nicely marked and heavy milkers. 100 2-year-old heifers due to freshen this Fall, and all in calf by registered bulls. You can pay more but you can't buy better.
F. P. SAUNDERS & SON, Cortland, N. Y.
Office, 50 Clinton Ave.

Purebred Registered
HOLSTEIN CATTLE
Quantity of production and persistency of milking during long periods are well-known characteristics of Holsteins. Dropping her first calf at about two years old the average cow, if well cared for, will produce from 5,000 to 6,000 pounds of milk in ten months, and she will increase the production every year until, at five years, she will give from 7,000 to 9,000 pounds.
If fed to their ability to digest and assimilate food, many Holsteins will exceed this production.

NEW ENGLAND MILK PROBLEMS.

ONE of the lines of investigation conducted by the agricultural committee of the Boston Chamber of Commerce is a trip by Secretary Orcutt and others over all railroad routes bringing milk into Boston and other New England cities supplied by car milk. All possible information in regard to cost conditions and all other things that affect the business in any way will be studied and looked into thoroughly. Railroad transportation is an important part of the business, and some of the truth of the matter should be got in this way. If the city end of the milk business is looked into as thoroughly as the country end apparently will be, we shall certainly know more about the whole situation than we ever did before. Conditions are changing all over New England all the time, and changing fast. As an illustration of this change our minister made a social call a few days ago and told the following in regard to a town he formerly preached in: In his time about 400 people, mostly farmers (as this was a farming town in the main) attended church the year around. Now 40 to 45 are the most to go at present time in the Winter season. Why this falling off? Simply because the former people have got sick of farming conditions in many cases. A few of course died and the places have been put on the market and purchased by the class of people who do not farm to produce anything, except mostly for their own wants in the short Summer season, while they are there, as in the Winter they return to the city. They are mostly Summer people from Springfield, New York, etc. These people of course have improved these homes and increased the taxes to a certain extent, but social life is dead a good part of the year; not a good live community as was formerly the case. The same thing is going on more or less all over many sections of New England, and in many cases it is largely former milk producers who by reason of past and present bad conditions are selling out or changing from a large farm to a small one, or turning entirely to depend on fruit, mainly apples, for their future income.

In the light of their true conditions here stated, something must be done without delay to better conditions along the line of milk production, and I believe good will come from the work now started and to be continued along these and other lines. Another illustration of the unstable and constantly changing milk conditions is the following: A certain milk collector, that is a man who gathers the milk for a contractor from the neighborhood farmers and carries it daily to the Boston shipping station, gives these figures for the past five years of collecting: His average load for the first six months was 45 cans per day; the following six months 30 cans; then new dairies were bought up, and 60 to 70 cans were carried for a period. Then one or more dairies were dropped by inspectors for some reason, perhaps a good reason, perhaps not; then one or two more sold out or went out of business, and the route was back to 40 cans per day. Then it dropped in a few months to about 30 cans or less. A year later a slight gain was made, then another contractor bought part of this milk and two teams had to be run to collect this small amount of milk, as one contractor would not let his milk be carried by the team of the other contractor and so it went first up, then down. Finally one of these contractors gave up, and it all went to the new contractor. At present time by getting a new dairy or two the route is up to from 60 to 70 cans in the flush time, and down to 50 or lower at others. Prices varied during this time from 23 cents in Summer to 28 in Winter, up to 35 in Summer and 45 in Winter, and then again down to 23 cents per can in some cases the present Summer in the low months, and about 37 or 38 cents last Winter.

Until we can have a standard price and an average supply these changes will keep on, and this is one of the big problems we must work out, to have conditions stable and know about what we shall produce and price we shall receive a few months ahead, and plan our business to meet what is coming. The day of doing business on guesswork is largely past. Formerly in the milk producing sections about every farm therein sold more or less milk, and a load was obtained within driving distance. Now half of these farms, in some cases more, in others less, are producing market milk, and the amount now produced does not pay to own a team in many cases, so the result is those who make enough milk to pay and who live not far from the point of delivery, carry their own and perhaps a few of the neighbors' milk; the others have no way to get their milk to this point, and not being able to deliver it themselves drop out. These are some of the reasons why the contractor has to go back much farther to get his supply.

A. E. P.

Value of Skim-milk.

WHAT is the value of skim-milk for poultry food, and what is it worth for pig food as compared with commercial feed stuffs? E. V. F.
Liberty, N. Y.

Skim-milk is a valuable poultry food, especially when fed soured. It is usually considered worth from 25 to 30 cents per hundred weight. Hoard's rule for finding the value of skim-milk fed to fattening hogs, as quoted by Henry, is: Multiply the market value of live hogs in cents per pound by five to find the value of skim-milk fed alone. If fed with corn or barley, it is worth more and the multiplier should be six. This gives the value of 100 pounds of skim-milk. Thus, if hogs are worth five cents per pound, live weight, skim-milk is worth 25 cents per hundred fed alone or 30 cents if fed with grain. Another rule is, the value of skim-milk when fed with corn to fattening hogs is half the price of corn per bushel. In feeding skim-milk to any animals, whether fed sweet or sour, the utensils used should be kept clean. Sour milk should not mean milk that has been kept under filthy conditions until it has become putrid. M. B. D.

The Milk-can Law.

ON page 934 I read of the complaint of one of your subscribers who has been sued for a penalty growing out of his use of a milk can. About 10 years ago, a firm of lawyers with whom I then had an office, had a similar case. The facts as I recollect them were these: A restaurant keeper was using an old milk can as a garbage receptacle. The same Mr. Walsh that you refer to in your article was the complainant, and agreeable to his usual practice, he brought suit in Orange County. Not caring to submit to such tactics, we defended the suit and I went up to Newburgh to try the case. Mr. Walsh sent some attorney to court with some excuse for delay, and upon my explanation of the facts, the judge granted the adjournment only on condition that Walsh would consent to transfer the case to Kings County. Some time thereafter the case came on for trial, Walsh defaulted and we took judgment against him for the costs. I do not believe that the judgment was ever paid. There is a case in the early Appellate Division Reports which at that time, in our opinion, precluded a recovery by Walsh. Of course I do not know the merits of your subscriber's case, but I am very sure that it would repay a little investigation on your part, and if your subscriber has some old-fashioned American blood in his veins, I think that he would derive considerable satisfaction from defending the suit, even though it might cost him more than to pay up. The law in question may be a just law, but the provision that a man can be sued for a penalty hundreds of miles from a county in which he lives is more conducive to blackmail than it is to the proper administration of justice.
New York. WALTER E. WARNER.

THE enclosed clipping taken from a Provincetown paper may have some bearing on your correspondent "A. E. P.'s" letter on milk production in Massachusetts. As a matter of fact it is difficult to overrate the decrease in the amount of milk prdouced in this part of Massachusetts.

"The number of cows in Truro has decreased 50 or more during the past year, and a milk famine is in sight during July and August. If you have not engaged a regular supply, do so at once—or you may be obliged to go without. Ten years ago there were over 230 cows in Truro, now there are 100 or less. Unless the farmer receives a radical increase in the price of milk in the near future, it will be only a few years when Truro will consume all the milk it produces." E. C. M.
North Truro, Mass.

FEEDING PROBLEMS.

Methods of Horse Feeding.

IS it best to give horses their grain first and hay afterwards or hay first and grain an hour or so afterwards? I give them hay at 5 a. m. and grain at 6 a. m., grain at 12 noon, no hay, and then give hay at 6 p. m., and grain last thing at night. What is the best system?
Danville, Pa. I. W. H.

You are feeding just right. Hay is not digested to any great extent in the stomach, which holds only three and one-half gallons. It passes along the small intestine (72 feet) and lodges in the large intestine (colon). Grain and concentrates, on the other hand, are mostly digested in the stomach and must not be pressed out of the stomach by hay, or washed out with water. Water first, hay second, grain third, is the theoretical rule of feeding. You might improve your method by allowing one or two pounds of hay at noon, when the horses are cooling off, then allow grain. If the horse cannot be left long in the stable at noon, in hot weather, better not feed any hay.
A. S. A.

Ration for Pigs.

WILL you advise on feeding my five pigs? I have but little skim-milk; am feeding a slop of mixed feed six quarts a day and three quarts of whole corn, also oat and pea fodder, cut green and thrown to them. They do not seem to grow very fast. H. B. F.

Although you do not state the age of your pigs I should judge from your description of the way you are feeding them that you started to feed whole corn before they had reached the proper age to digest it thoroughly. When this is done indigestion usually results and a gradually weakened condition follows. The remedy is to discontinue feeding the whole corn and substitute about 10 per cent. of fine ground cornmeal mixed with the slop of mixed feed. Continue feeding the oats and peas as long as they are tender enough to be eaten with a relish and give free access to good drinking water every day. A little pulverized charcoal mixed with the feed will help to correct the trouble. C. S. G.

Ration for Milk.

WILL you advise a balanced ration for a Jersey cow that will insure a good flow of milk? I have plenty of Alfalfa hay, but no silage, and wish to feed a right proportioned grain ration with it. T. W.

Unfortunately, no balanced ration can insure a good flow of milk; it can only insure that the cow shall have the necessary materials from which to make milk to good advantage if the ability to do so is bred and born in her. With plenty of Alfalfa hay, it is not necessary to feed as "narrow" a grain ration, or one rich in protein, as is usually recommended. This is an advantage as the high protein grains are the most expensive ones. Equal parts of cornmeal; mixed wheat feed and gluten feed would make a good grain ration for this cow, to be fed in the quantity of one pound per day to every three or three and a half pounds of milk that she is giving. Ground oats, corn and cob meal, or dried beet pulp might be substituted, in whole or in part, for the corn meal; wheat bran for the mixed wheat feed, and brewer's dried grains, malt sprouts or buckwheat middlings for the gluten feed. There is no one best ration and the relative prices of the different available grains should govern the choice to a certain degree. If a cow loses flesh too markedly while in milk, cornmeal should form part of her rations, and if she has no succulent vegetable food, the dried beet pulp is helpful. M. B. D.

WHEN you write advertisers mention THE R. N.-Y. and you'll get a quick reply and a "square deal." See guarantee editorial page.

The Henyard.

THE EGG-LAYING CONTEST.

CONTRARY to expectations, and notwithstanding that molting has begun—nine Leghorn pens have molting birds—the fortieth week shows a gain of 71 eggs as compared with the previous week. English White Leghorns again lead all other pens, with a score of 59 eggs. Bonnie Brook Farm's White Leghorns tie with A. B. Hall's Barred Rocks for second place in the week's record, each pen laying 53. The "sour milk" pen of Leghorns from Storrs Agricultural Station takes third place, with a score of 52. This pen is now the leading pen in the total score, having laid 1,689 eggs, Barron's White Wyandottes scoring a total of 1,676. Francis F. Lincoln's pen of Leghorns are third with a score of 1,665. Mr. Barron thinks that his Wyandottes will lay enough better than the Leghorns toward the close of the contest, still to give them a fair show of winning. For the first time in several weeks two breeds besides White Leghorns have laid 50 or over. A. B. Hall's Barred Rocks laid 53, and Merrythought Farm's White Wyandottes laid 51. The total score now is 94,510. The week's record follows:

GEO. A. COSGROVE.

"Do you keep a pistol in your house?" "Yes. I've had one for twenty years." "Ever need it?" "No." "Then why keep it?" "It comes in handy. Sometimes ma uses it to drive tacks."—Detroit Free Press.

Breeding the "Egg Type" in Hens.

I WANT to give you my opinion of Tom Barron's Wyandottes. Mr. Barron says his smaller birds were always the best layers, and I think his Wyandottes are smaller than ours. We have three classes of fowls, very large ones like Brahmas and Cochins, which are kept principally for meat, medium-sized ones, like B. P. Rocks, Wyandottes and R. I. Reds, and the smaller ones, like Leghorns, the medium-sized ones kept for general purpose fowls and smaller ones for eggs. The same is true of cattle. We have beef cattle, general-purpose medium-sized cattle, and small Jerseys for butter. Supposing a breeder of beef cattle should pick out his best butter and milk cows and breed from them. They would be smaller or at least of dairy type, and after a few years his Angus or Shorthorn cattle would be as small as Jerseys, and Jersey or dairy type. What has he gained? He has spent years of time making a Jersey from a Short-horn when he could have bought a Jersey at first better than he has made. I think Barron has done this with his fowls; he has selected from good-sized Wyandottes for

POULTRY ENTHUSIASTS AT THE CONNECTICUT EGG-LAYING CONTEST.

eggs, which meant small birds, and if he keeps selecting in that way will have eventually a bird the same size as the Rose Comb Leghorn, which will be to all intents and purposes Leghorns, when he could have saved all the time and labor by getting R. C. W. Leghorns in the first place. I always think of the Wyandottes as a broiler fowl, and if they are bred for eggs we get away from that type and to layer or egg type.

I think breeders have done us good service in having a standard for both cattle and fowls, and in keeping as near to it as possible. We must have some kind of distinction between large and small fowls, and then take whichever we prefer, and line-breed it as near standard as possible. If we want eggs take the Leghorn, and if we want a nice fowl to sit and for a good table fowl take a Wyandotte. Butchers have told me that the rounded compact White Wyandotte was the best table fowl they knew of. If we want a very heavy table fowl the Light Brahmas or Cochins will fill the bill. I cannot see any gain in breeding one smaller or the other larger, or mixing breeds. I think Mr. Barron's Leghorns will beat his Wyandottes after a while anyway.

Virginia. EUGENE R. SKIDMORE.

Destroying Hen Lice.

HOW can I rid a henhouse of lice? We just bought a new sprayer holding eight gallons, sprayed the henhouse all over, nests and all, with whitewash, using about 30 gallons, but it seems to have done no good. The floor is dirt and it is alive with lice; our feet are covered with them every time we go to the henhouse. R. W. F.

Orwell, N. Y.

The loose litter upon this floor should be removed and burned and after scraping the floor it may be well covered with fine road dust or ashes or sprinkled with air slaked lime. Lice will not survive contact with fine dust of any kind and sifted coal ashes make an excellent application to floors, droppings boards and other places where lice congregate. The addition of from four to six ounces of crude carbolic acid to each gallon of whitewash, added while it is hot, makes it a more effective insecticide for use in the poultry house. M. B. D.

Trouble With Chickens.

I HAVE a new trouble with chickens; I have never noticed it before this season. They seem to lose use of their legs, walk short distances and tumble over on side and are unable to get up. If set up on feet then walk all right and fall over again. What is the trouble and remedy? They eat heartily, comb red, seem healthy in every other respect. Those attacked are about size of partridges, some smaller. They are in dry clean quarters and have fine range.

Elk Hill, Va. J. E. E.

These fowls are probably suffering from attacks of vertigo induced by attacks of indigestion, the presence of intestinal parasites, or possibly by exposure to the hot sun and overfeeding. They should be given plenty of shade and fed more sparingly if it is thought that they are overeating. One or two teaspoonfuls of castor oil administered to any bird showing symptoms of the trouble is good individual treatment, and if intestinal parasites are thought to be present a teaspoonful of oil of turpentine may be mixed with the oil. M. B. D.

Indian Runners for Eggs.

HOW long can Indian Runner ducks be kept without having their laying qualities impaired? If properly taken care of do they compare favorably with chickens for profit in the matter of egg production? R. S.

Pennsylvania.

A vigorous Runner duck ought to lay well till six years old or older. They vary like individuals of other species. Ducks' eggs contain more nutriment than hens' eggs, principally on account of the greater size, and bring a higher price with those who appreciate them, but the market for them is limited. There is a prejudice against them on the part of many American women. Raising show birds and selling eggs for hatching is more or less profitable. Producing eggs for the general market is a different proposition. If you are near a sure market and like ducks there would not be much risk in trying them. It should be borne in mind that exceptionally good layers are scarce among ducks as among hens. It costs more to feed a duck than a hen. On general principles I would advise sticking to hens. W. H. H.

Washed Eggs.

WE have had letters from a number of egg dealers, who urge us to tell our readers not to wash their eggs, especially during the warm weather. It would seem that some shippers who are eager to make a good showing with eggs scrubb them with a brush and then ship. The dealers claim that this is just the thing that they ought not to do as this hard washing takes off the enamel or polish from the outside of the shell where Nature put it as a precaution. The stains, of course, should be wiped off the egg, but the plan of scrubbing the egg all over is a bad one to follow, and especially in warm weather.

PLEASE tell the woman whose turkey eggs will not hatch that I have found that when the turkeys are too fat that eggs will not hatch. I have reduced the feed of turkeys and had the next clutch hatch. L. E. W.

New York.

PUBLISHER'S DESK

The various transportation companies are standing rather firmly upon that clause of their receipts pertaining to filing claims for loss and damage within four months after a reasonable time of delivery has elapsed. It will be well to bear this in mind, and see that claims are entered within the prescribed time. Make prompt investigation if returns fail to reach you from houses to whom you are shipping, and ask your agent to trace the claim promptly. This will act as a waiver, and when formal claim is entered the companies cannot fall back upon the time limit as a technicality for declining the claim. Losses prior to February 9, 1914, will not be considered by transportation companies if no notice was given of the loss prior to April 1, 1914.

A jury in the United States District Court acquitted Nova Adolphus Brown, Floyd N. Franklin and seven other defendants who were charged with using the mails to defraud in the sale of $650,000 of the stock of Franklin's Inc., a candy making concern, with headquarters in Long Island City. The jury had been out 27 hours and had twice reported its inability to arrive at a verdict, only to be sent back to its room by the judge. At first, it is said, only one juror held out for the acquittal of all the defendants. Judge Russell had the jury locked up for the night and the defendants sent to the Tombs. Until an hour or so before the verdict it was rumored that three jurymen were voting for a general acquittal. The trial lasted for three weeks.—Local Paper.

The promoters will probably point to this verdict as a justification of themselves; but the victims of the schemes have lost their money, and no verdict of a jury, either for conviction or acquittal, will alter their sad position. A failure to convict is by no means a clean bill of health for the scheme. It may be that one or more of the jury are in sympathy with crooks, or it may be that the evidence is such that honest jurymen have a doubt as to the fraudulent intent of the promoters. No matter how foolish and impractical a scheme may be, if the jury thinks the promoter might have believed that it would be successful, they must vote for acquittal, no matter if he humbugged every investor in the scheme. Their lawyers frankly admit the failure of the scheme. Sometimes they call it the vision of a dreamer, but insist that it is no crime to dream. Juries often become very squeamish on this argument and it has kept a good many promoters out of jail. The only help for the victim must be administered before he parts with his money. After it once leaves his hands the case is hopeless. That is why we try to sound the warning to our people in advance.

On July 9, 1914, after considerable correspondence I sent W. O. Chase of "the Edgemont Poultry Farms" of Hillsboro, Ill. $15 for 100 R. C. Black Minorca day-old chicks which were to be sent me at once. I have written him at least a dozen times since then and demanded that he either return the money or send me chicks. Sometimes he has answered with excuses and promises but nothing else has been forthcoming. I wrote the local banker there, and he said Chase was slow. If you could get anything I would be very glad, and if not, you might show him up for the benefit of your subscribers. H. E. H.

Pennsylvania.

We also have complaint from a New York State subscriber who sent this same W. O. Chase of the Edgemont Poultry Farms, Hillsboro, Ill., $15 for a pen of poultry last Spring. Mr. Chase failed to ship the poultry as agreed, and our efforts to get any adjustment in either case has been fruitless. Mr. Chase seems to be in the same class of poultrymen as E. E. Cooley of Ransomville, N. Y., and E. F. McAvoy of Cambridge, N. Y. We trust THE R. N.-Y. readers will give all three a wide berth in the future.

I am sending you literature which rather puzzles me. I don't know whether I have a good friend who wants to make money for me, or has my name on his sucker list. However, I did not send any money. It is a new one to me. If you think it a swindle please expose it. If all right, why give the gentleman due credit for his generosity in wanting to help a farmer. Having read the contract carefully, it looks very one-sided. C. S.

Indiana.

The literature enclosed is from the Ozark Hog Ranch Co., of St. Louis, Mo., which appears to be a scheme to sell two brood sows in connection with 10 acres of land for $225. It might be called a sale of land with the brood sows thrown in or a sale of the brood sows with a bonus of the land. It would not be so much a surprise if the scheme appealed to city men who have no knowledge of farm operations or stock raising, but we doubt if such bait will catch many farmers.

Dwight B. Cornell of the Cornell real estate agency of Great Barrington, and the head of that institution, was arrested Friday and placed under $500 bonds to answer to a charge of false pretences, brought by T. S. James of Austerlitz, N. Y. The substance of the complaint is that Dwight B. Cornell obtained the signature of T. S. James to a written instrument designedly and with intent to defraud Elmer C. Herrick of Great Barrington. It seems that Mr. Herrick was the owner of a farm at Austerlitz, N. Y. Mr. James was the proposed buyer and Cornell acted as agent. On Oct. 17, 1911, it is alleged, Cornell agreed with Mr. James for the purchase of the farm for $1,600; but on the next day wrote Mr. Herrick that he had been offered only $900 in cash or $1,000 in credit.—New York Local Paper.

Of this particular transaction we know only what is reported above; but we have had occasion to refer to Mr. Cornell's operations in the past on different occasions; and the practice of some agents in selling farms at 20 to 70 per cent. above the owner's price and keeping the excess as commissions or profits, has been quite freely discussed in these columns. Several civil actions have resulted in the courts; but this is the first criminal action that has come to our attention. The precedent established by this action will be important; but it is usually difficult to convict in such cases on criminal charges. The people however will find some way to reach the agents who persist in these practices. The civil courts do not afford a remedy because they are too expensive for the class of people who are deceived. If the criminal courts do not reach them, statutes will have to be enacted to regulate the sale of farm property through agents, and they will limit the commission to the agent and prescribe the form of contract to be used.

I have watched THE R. N.-Y. closely for the past year, and I find you are a real protector of your subscribers. I am in trouble with the Verde Grand Copper Company of Arizona. The leading men are trying to freeze the stockholders out. I have 1,250 shares non-assessable. I never refused to do my part. They fixed a mortgage for $4,000; placed it in the Jerome Bank to come due February 15, 1915, in this way trying to take the mining outfit, which has cost at least a few hundred thousands. What can I do to protect myself? I was told by a man, who knows all that country, that the mine was O. K. Could you collect $10,000 from the officers for my claim? G. W. S.

California.

In 1910 one of our subscribers reported a sad experience with this same Verde Grand Copper Company. We wrote the president of the company in regard to the present complaint and he advises us that the stock has but little value in the market—one-half to one cent per share, and there is but little sale for it at any price. The stockholder simply owns a fractional part of the business of the company. The other stockholders have as much legal right to collect their original investments from him as he has from them. Of course, really the promoters usually manipulate things for their own advantage, and by a control of the company get all the benefits. In mining enterprises there is seldom any attempt to develop the business; but when there is, and the mine becomes valuable, the small investors are usually frozen out. We are powerless to help in such a situation.

The inclosed card gives address of the Associated Farm Products Co., Herald Square Building, N. Y. City, that has a representative soliciting shipments of eggs and offering attractive prices for same. They are anxious for immediate shipments. Do you know anything about them? Do you consider them a safe consignee? E. E. R.

Manorville, N. Y.

Several shippers have inquired about the Associated Farm Products Co., which according to the best information we can get is the name assumed by a Chas. A. Boyle. He is reported to have desk room at the address given and to be engaged in selling eggs to private families. He carries no stock and we are unable to learn through the regular channels that he has any financial responsibility. The only safety for shippers therefore will be to insist on advance payment or some tangible form of security before parting with their produce.

Products, Prices and Trade.

Wholesale Prices at New York,

Week Ending Aug. 14, 1914.

MILK.

The Borden milk schedule to producers for the six months beginning with April is as follows, compared with last year. This is per 100 pounds in the 26-cent zone. For the 29 and 32-cent zones the schedule is 10 cents less for all months:

	1914.	1913.
April	$1.40	$1.50
May	1.15	1.25
June	1.10	1.10
July	1.25	1.35
August	1.40	1.45
September	1.50	1.55

Figuring 86 pounds to the 40-quart can the per quart price is as follows: April, 3.10 cents; May, 2.47; June, 2.36; July, 2.68; August, 3.01; September, 3.22.

Wholesale prices paid by New York dealers are running $1.61 and $1.51 for B and C. Hotels and restaurants using two to three cans per day are paying five to 5¼ cents per quart, single quart prices from bakeries and grocery stores, six to seven cents; delivered milk, nine to 10 cents.

BUTTER.

The market on all grades of creamery is firm and one to two cents higher. Business is better than last week. The packing stock arriving is mainly poor.

Creamery, extra, lb	29½	@	30½
Good to Choice	25	@	29
Lower Grades	20	@	22
State Dairy, best	28	@	29
Common to Good	18	@	25
Factory	19	@	22
Packing Stock	18	@	21

Elgin, Ill., butter market 28½ cents.
Philadelphia, western creamery, 31 cents.

CHEESE.

Prices on imported stock will be dropped for the present, as supplies are scarce and practically nothing new arriving. Domestic cheese of most grades is one cent higher than last week, the market for white being less firm than colored.

Whole Milk, fresh, specials	15¾	@	16
Average fancy	15	@	15½
Prime	14¾	@	15¼
Under grades	10½	@	14½

Skims, specials	11¾	@	12¾
Good to choice	10	@	11½
Poor to fair	5	@	10

EGGS.

A limited trade is noted in fancy white eggs at one cent above last report. Qualities below this are in ample supply, showing a considerable proportion of heat damage. A few eggs are being shipped to England this week, upwards of 15,000 dozen.

White, choice to fancy, large	33	@	34
Common to good	25	@	32
Mixed colors, best	28	@	30
Common to good	18	@	22
Western fresh, white	24	@	28
Lower grades	18	@	20
Storage, best	26	@	27
Lower grades	19	@	24

FRESH FRUITS.

The market has been overstocked with windfall and low-grade apples. Hand-picked Yellow Transparent and Duchess bring $1.50 to $3 per barrel, the latter price rather exceptional. Peaches selling well and slightly higher for fairly colored sound fruit. Some shipments of windfall peaches have been seen. They may seem of some value when picked up, but are sure to spoil on the way. Blackberries, huckleberries going at improved prices, some of the latter arriving from Nova Scotia, wholesaling at 16 cents per quart.

Apples—Alexander, bbl	1 50	@	3 00
Yellow Transparent	1 50	@	3 00
Duchess	1 50	@	2 50

GRAIN.

The wheat market has had some wild advances and drops during the week, based on the probabilities of shipments to Europe being resumed. It appears quite certain that sales to the other side can be financed by exchange through gold deposits in Canadian banks, but sellers are uncertain as to insurance of cargoes even where ships are to be had. It seems probable that within a week or two some satisfactory arrangement will be made.

RETAIL PRICES AT NEW YORK.

The figures given here are not the highest or lowest, but fairly representative of many thousand sales in New York where the buyer takes the goods home instead of having them delivered. Fruits and vegetables at New York are retailing lower than for many years, as there has been a large supply throughout the season. Meats of the same quality vary widely in price, depending on the expenses of the retailer and his ideas as to profits, some being ready to do business on a much lower percentage than others.

August 6. We have had an abundance of rainfall in this section this year. Crops are looking the best they have in several years. Haying is nearly all done, with a little larger tonnage than last year. Pastures are holding out well, and cows have kept up the milk flow better than commonly. The milk companies are riding the country looking for more milk; they say the milk has dropped off nearly one-half in quantity since the flush of feed. If they would advance the price a little that would encourage the dairymen to feed more grain, and more grain means more milk. Pea picking is at its height just now and prices are running very low, mostly selling around 50 and 60 cents, with a few sales running $1 per bushel. We would like to know what the consumer is paying for them. It is estimated that this county has produced 300,000 cases of eggs in the last 12 months with prices a little better than a year ago. Hog cholera has broken out in several places in the county, and it is advised not to exhibit swine at the fairs this Fall. M. W. F.

Otsego Co., N. Y.

BOSTON MARKETS.

BOSTON market is in a slump, various causes have brought this about. The shutting off of our export trade at this time, just as our apples are coming on the market, is very bad, especially as there is practically no other outlet for these as all other markets are supplied by the general good crop all over the country. Native stock, mostly drops, brings 50 cents to $1 per box, a few good ones $1.50 or better. The market is flooded with cantaloupes, and these are sold at whatever is offered, in many cases from $2.50 down to $1 per crate, and are retailed out at three for 25 cents in most cases, but many are offering them at five for 25 cents to catch trade. California pears $2.50 per box, natives not yet ready. Peaches plenty from Southern sections and are selling at $2 per bushel basket for best, in other cases good fair fruit goes at $1 per bushel basket and around $2 per crate. Oranges a little short and bring $3.50 and better per box. Lemons about $7; watermelons 25 and 35 cents each. Blueberries in fair supply at 10 to 15 cents per box, other berries in scattering lots sell at 14 for blackberries, 5 and 10 per box for currants, and 10 cents per pint for raspberries. All kinds of vegetables plenty and in most cases low in price. Local grocers complain of too heavy shipment from Connecticut as one of the chief causes of the surplus and low prices. Green corn is cheaper than usual at this time of year, only bringing 50 to 75 cents per box in most cases; quality fair and size rather small. String beans bring any price from 25 to 50 as the rule. Cabbage about 60 cents per barrel. Good cucumbers about $1 per box; beets 1¼ and 1½ cent per bunch; lettuce 15 cents per box in many cases. Onions dropping from the $2 price of a short time ago to $1.50 and $1 per box. Potatoes a little more plentiful and price getting reasonable, $1.50 to $1.75 per barrel and 80 to 90 cents per box. Sweets $4.50 per barrel. Tomatoes, outdoor, $3.50 per box, indoor 10 cents per pound. Squash $2 per pound for marrow; Summer about 60 cents per box.

All meats are being held at higher prices and consumption of these is falling off, eggs being used freely. Beef, dressed, brings 14 to 18 for best cuts, others 10 to 12. Best lamb 18, others 9 to 15. Dressed hogs 11½. Live beef or native stock at Brighton 7 to 9 for good, others 5 to 7. Live hogs 9½, live veal 9½ per pound.

Hay is not offered freely and brings $25 for best per ton, other grades down to $15 per ton. Grain on the jump. $1.80 per bag for meal and corn; cottonseed $33 per ton; gluten $30; linseed $32 to $34; bran $28; mixed feed $30; oats 50 cents per bushel. A. E. P.

Subscribers' Exchange

WANTED—Farm of about 80 acres, 40 acres tillable; must have orchard, running water, woodland, pasture, dwelling and outbuildings, about 100 miles of New York City; no agencies. Address F. E. SCHEEL, 433 West 46th St., New York City.

FOR SALE—3,500 acres ranch, 400 acres in farm, 3 sets improvements, 4 silos, 1,526 acres deeded, balance leased; deeded land, $14 per acre, lease thrown in; crop, live stock and equipment put in at reasonable price. E. D. HUNT, Owner, Childress, Tex.

FOR SALE—Good 80 acre farm, fair building, 50 acres improved, balance good timber and pasture; telephone and R. D.; good neighbors; ¾ mile from school, 2½ miles from two small town and Erie R. R.; price, $2,400; reason for selling, other business. Address the owner, WALTER BEERS, Cameron Mills, N. Y.

FOR SALE—A seventy-acre dairy farm, located in West Brookfield, Mass.; near first-class markets, schools and churches; twelve-room house, 65-foot barn with basement, carriage house, orchard, running water to house and barn; year's supply of stove wood; large flock hens, two shotes, seven cows, two horses, necessary farm machinery in good condition. This is a splendid farm and would make a nice summer or all-the-year-round home; plenty of fine shade trees, sightly; American neighbors; a good place to live; been in the family over sixty years. Terms easy. Price $6,000; no dealers. Write or see H. W. KING, East Longmeadow, Mass.

Subscribers' Exchange

Complying with several suggestions received recently, we open a department here to enable RURAL NEW-YORKER readers to supply each other's wants. If you want to buy or sell or exchange, make it known here. This Rate will be 5 Cents a word, payable in advance. The name and address must be counted as part of the advertisement. Copy must reach us not later than Friday to appear in the following week. No display type used, and only Farm Products, Help and Positions Wanted admitted. For subscribers only. Dealers, jobbers and general manufacturers' announcements not admitted here. Poultry, Eggs and other live stock advertisements will go under proper headings on other pages. Seed and Nursery advertisements will not be accepted for this column.

POSITION WANTED—By married dairyman, milker and butter maker. Has small family. Reference. PATRICK DONOVAN, Hope, R. I.

AMERICAN—Single, first-class carpenter and painter; also experienced gardener, wants position on gentleman's place or institution. E. C., care R. N.-Y.

YOUNG MAN—Some experience with cows, horses, garden truck, etc., wants position on practical farm, with good home. Address SULLIVAN, 7 W. 92nd St., N. Y. C.

POSITION WANTED—On private or commercial poultry farm, by single man, 27; 4 years experience; can run incubators and brooders; good on winter egg production; best of reference. A. E. EDWARDS, Jermyn, Pa., R. 1.

PRACTICAL FARMER—Wants position as manager; capable of, and to be trusted with, entire charge of gentleman's estate; married; acquainted with up-to-date methods and machinery; references exchanged. P. S. H., care of Rural New-Yorker.

POSITION WANTED—By experienced single man; understands creamery work, testing, production, sanitary milk, care and feeding cattle, general farming; first-class buttermaker; college training; practical and sensible; references. Address DAIRYMAN, care Rural New-Yorker.

FARMER—Young married man, with life experience in general farming and dairy, wishes to correspond with parties in need of a reliable man; have been employed as foreman of an up-to-date business dairy on Long Island for two years, where my services have been absolutely satisfactory. Address BENJ. DAVIS, Roslyn, L. I. Box 116.

POSITION WANTED—As manager for farm or estate; would take good dairy farm on shares, thoroughly understand farm crops, up-to-date machinery, steam and gasoline engines, tractor plows, concrete work; New York State preferred; strictly sober, reliable, married American; small family; good references. Address Energetic, Care R. New-Yorker.

WANTED—Man and wife; man must be feeder and milker, and do general farm work. Wife to work in house. Farm just outside city of Poughkeepsie. Modern improvements. House left in entire charge of couple from October to May. Give names and addresses of persons who know your ability to fill position and wages expected, in first letter. JOHN G. PHEIL, 52 Broadway, New York City.

A METHODICAL, practical, scientific and successful general farm and dairy manager covering years of extensive and varied experience in exacting operations will be open for engagement Sept. 1. Eminent credentials will be furnished and nothing short of a first-class, responsible and remunerative position will be considered. If desirous, might consider cash proposition of lease of entire property. Address T. J. A., care Rural New-Yorker.

ALFALFA HAY—F. P. ERKENBECK, Fayetteville, N. Y.

FOR SALE—For want of use, cow-pea harvester, cuts, threshes, cleans, in one operation, horse driven; price, $70. W. LERCH, Supt., Scobeyville, N. J., via Eatontown.

SOUR CHERRIES in No. 2 cans, syruped with pits, $1.25 per doz.; Clapp's favorite and Bartlett pears in No. 2½ cans, with syrup $1.50 per dozen. SENECA FRUIT FARM, Waterloo, N. Y.

FIG PRESERVES—Home made; a new delicacy for most people; made from choice fruit right from the tree; few people have ever tasted a fig as it ought to be; write for prices and sample to MRS. M. A. PARKER, Rickerly, near Dauphin way, Mobile, Ala.

FARM WANTED—Columbia County; must be bargain; fullest information. Address C. R. H., care R. N.-Y.

10 ACRES—House, barn, hen houses, outbuildings, orchard; price reasonable. W. P. TAYLOR Oradell, N. J.

FOR SALE—235 acres, good soil and buildings, fruit and stock farm in fine condition, $35 acre. Inquire T. S. PAGE, Cohocton, N. Y., R3.

FRUIT, TRUCK, POULTRY FARM—Will sell all or any portion of 36 acres; good buildings, excellent location; immediate possession; no agents. HOMER TWEED, Quakertown, Pa.

FOR SALE—The Mattituck White Leghorn Farm. A new plant, fully stocked and equipped. Will net annually 25 per cent. of purchase price—$8,000. ARTHUR H. PENNY, Mattituck, N. Y.

ON POCOMOKE SOUND, Eastern Shore of Maryland, mild, healthy climate, 500 acres fertile soil, beautiful home and buildings; salt water front; oysters, fish, crabs, clams and game plentiful. Will sell at a bargain, or would lease to a party that would buy the crops, stock and farming machinery. Address OWNER, Box 23, R. F. D. No. 2, Marion Station, Somerset Co., Maryland.

REAL ESTATE FOR SALE—Massachusetts—A bargain—Farm and mill, 200 acres in lovely valley, 2 two-story houses, 2 barns and outbuildings, 80 acres wood, 20 acres pine, crops in; farming tools, 80 apple trees, 16 cattle, 2 horses, fowls, bees, mill complete, circular saw, shingle machine, planer, matcher, rip saw and wood splitter; 3 miles from town. Boston & Albany railroad station; 2 lines of trolley. Inquire of BOX 413, West Brookfield, Mass.

DO YOU NEED FARM HELP

We have many able-bodied young men both with and without farming experience, who wish to work on farms. If you need a good, steady, sober man, write for an order blank. Ours is a philanthropic organization and we make no charge to employer or employee. Our object is the encouragement of farming among Jews. THE JEWISH AGRICULTURAL SOCIETY, 176 Second Avenue, New York City.

Corn Insurance

is the title of our Free Catalog which tells how to take proper care of your corn crop. With plenty of illustrations and testimonials it proves to every business-farmer that it pays to invest in a

Marshall Corn Crib

It protects your corn against loss through fire, vermin, inclement weather and theft. The perforated body of crib and the ventilating shaft insure perfectly cured corn. Built along scientific lines, easy to erect and everlasting. Comes in several styles and many sizes. Ask for the free catalog today.

Iron Crib & Bin Co.
Box 125 Wooster, Ohio

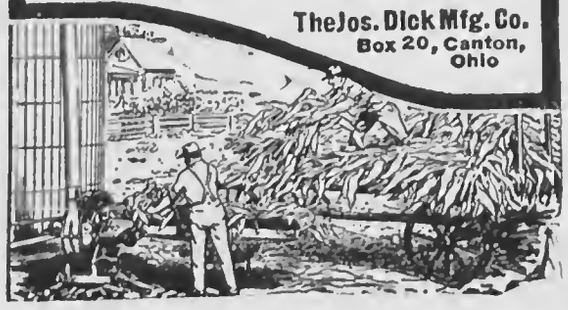
13 Years in use and still good

For thirteen years, Mr. W. E. Currie of Detroit, Mich., used a Blizzard on his farm. Last year he bought a new Blizzard with self-feed table. "My first Blizzard," he says, "is in good shape and will keep it for emergency in case of an overfeed of monkey wrench to the new one." The

BLIZZARD Ensilage Cutter

will give you long service, too. Your regular farm engine will run it and elevate high as needed. Eats up silage, dry or green. Self-feed table. Almost runs itself. Cuts evenly. Absolutely safe. Write for catalog.

The Jos. Dick Mfg. Co.
Box 20, Canton, Ohio



The New-Day Car

The HUDSON Six-40 for 1915 is the finest example you will find today of the new-type high-grade car. Go see how many advances it shows over the cars you know.

Howard E. Coffin was the chief designer. The whole Hudson corps of 48 engineers have devoted four years to this model. Since last year they have added 31 new features. Now it shows you in finished form the ideal coming car.

The Advances

The greatest late-year advance in motor construction has been the adoption of Sixes. That means continuous power. HUDSON engineers have done most to this end by making the Six economical.

They have made it light. This new HUDSON Six-40 weighs 2,890 pounds. Old-type cars of this power and capacity weighed around 4,000 pounds. We save you this difference, yet this car has proved itself one of the staunchest cars built.

A new-type motor used in the HUDSON has reduced fuel cost about 30 per cent under old-time averages.

The new-style streamline body is here brought to perfection. And here are many new refinements, new ideas in equipment, new comforts and conveniences. Some of the best HUDSON features are not yet found in any other car.

The New Price

This car also sets a new price standard for high-grade cars. Last year's model sold for $1,750. This year, to meet the demand, we shall build three times as many. Now this new model with 31 improvements is sold for $1,550, because of this trebled output.

There is no reason now, if you pay over $1,200, for not having a quality Six.

End of Over-Tax

This new HUDSON Six marks the end of over-tax. This lightness reduces tire cost immensely. This new-type motor brings down fuel cost. And the price is the lowest ever quoted on a car of the HUDSON class.

Go see what all these new things mean before you buy a car.

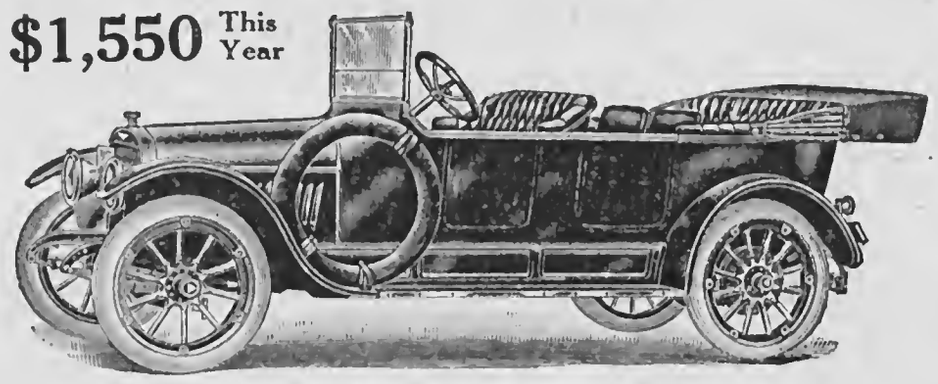
Hudson dealers are everywhere.
New catalog on request.

Some 1915 Features

A perfect streamline body.
Disappearing tonneau seats.
Invisible hinges—hand-buffed leather upholstery.
Gasoline tank in dash. Tires carried ahead of front door.
"One-Man" top with quick-adjusting curtains.
Dimming searchlights.
Simplified starting, lighting and ignition system.
Wiring in metal conduits.
Locked ignition and lights.
New speedometer drive.
Automatic spark advance.
New-method carburetion.
Trunk rack on back.

HUDSON SIX-40 for 1915

$1,550 This Year



This Phaeton body with room for seven, $1,550 f. o. b. Detroit.
Standard Roadster same price.

Hudson Motor Car Company, 8110 Jefferson Ave., Detroit, Mich.

Ellis Champion Threshers

Suit everyone. Both the professional thresherman or the farmer who wants a home outfit will find the Champion rightly named. The picture shows ELLIS CHAMPION No. 2. It is complete with stacker, tailings, elevator and grain bagger. Connect it with steam, gasoline, tread or any other power, put in the grain and the Champion does the rest. No straw clogging. Any size.

We also make tread and sweep horse-power, drag or circular saws, ensilage cutters, corn shellers, etc. Our catalog tells the whole story.

Be Your Own Thresherman

Save enough to own the Thresher. Be independent. Do the work when you get ready.

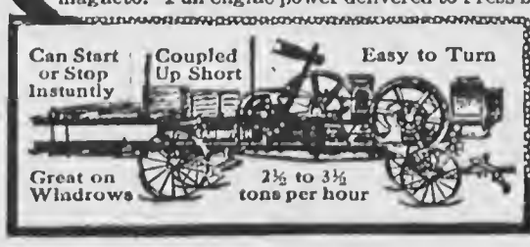
ELLIS KEYSTONE AGRICULTURAL WORKS, Pottstown, Pa.

Big Tonnage! Big Profits!

No delays, sure, certain operation. These are yours with the fast working Sandwich Motor Press. Many owners make enough clear cash to pay for their outfits the first year—$200 to $300 clean profit each month. One Sandwich owner writes he baled "32 tons in 8 hours with a 3-man crew." Another how he averaged $18 to $22 per day after paying all expenses. These men can do this because they have the right press. 20 years experience built into it and special patented features found only on the Sandwich press—these are the reasons Sandwich owners make more money than others. The Sandwich way, the sure way.

SANDWICH SOLID STEEL HAY PRESSES

SANDWICH Money Maker MOTOR PRESS has a hopper cooled gas engine mounted on same truck, 4, 6, 8 or 10 h. p., of more power than rated. Geared magneto. Full engine power delivered to Press by heavy steel roller chain. No power lost, no belts to slip or to delay. Simple self-feeder and the big feed opening just swallows the hay. Friction clutch right on press.



Free Book! The Way to Win

Send a postal today for our free catalogue "*Tons Tell.*" It gives you reliable figures of the cost and profits of the hay baling; shows all the Sandwich Hay Presses, both motor, belt and horse power. Also ask for our special terms so you can buy your press from the profits made the first year. Write Quick. Address Sandwich Mfg. Co., 119 Oak Street, Sandwich, Ill. Box 119, Council Bluffs, Ia. Box 119 Kansas City, Mo.

You want your Threshing done quickly and you want it done well
Clean, ripe grain threshes easy but it takes the quality of

CO-OPERATIVE SILO FILLING

Working in Groups of Farmers

PLANNING THE LABOR.—Silo filling is one of the rush jobs of the year. Where the silo has been in vogue so long as is the case in my community the "bunch" labor question has nicely adjusted itself. We work co-operatively. For several miles down the road and up the side lines as well practically every farmer has a silo. We have gathered into groups for silo filling sufficiently large to allow four teams in the field, two or three extra men to help the teamsters load in the field, a couple of men to feed the cutting machine, and from one to two men in the silo. These same groups of men have been working together so long now that everything at silo filling time moves like oiled machinery. We have proven in a small way that farmers can co-operate.

LIGHTENING HOUSEHOLD WORK.—Another feature about our silo filling that is worth mentioning is the fact that we have done away with the elaborate suppers that a few years ago always completed the day's work at both silo filling and thrashing. I can remember how the housewives in this section used to vie with each other to see who could put up the best meal for the visiting farmers or farm hands. These meals always represented a considerable monetary outlay, were a needless extravagance, and worst of all, they were a needless amount of labor for the farm women. Nowadays we stop work in plenty of time so that we can go home and get the chores done in good time, and we have our supper at our own tables. We have not yet cut out the friendly meeting around the neighbor's dining table at the noon hour. But cutting out the supper is easy.

Copyright by Underwood & Underwood, New York.

"CANDIDATES FOR THE LADY'S HAND." FIG. 447.

WHEN TO CUT.—I want to give some pointers that I have learned from experience on the filling of the silo. The first point is the stage at which the corn is to be cut. Most of us used to have the idea that corn for silage did not need to be particularly mature. In fact the first corn that I ever put in a silo had not reached the milk stage. It was green watery stuff, and in the Winter it was so sour and the stock showed such a dislike for it that I was almost inclined to dub the silo a "frost." I now value maturity in the corn for the silo. For some reason or other the cows milk better on mature silage, and it goes farther. The professors tell us that mature corn has much more food value, and they must be right. We used to cut the corn with corn knives, but for the last few years I and two of my neighbors have owned a corn binder co-operatively, and we would not be without it. In up-standing corn it does its work with neatness and dispatch. The corn is bound into bundles convenient for handling and for feeding into silage cutter. Even where the corn is blown down or lodged the modern binder has devices that enable it to do creditable work. I would advise every corn grower either to have a corn binder himself or a share in one.

CUTTING THE CORN.—In the field we plan to start the corn harvester half a day before the engine and cutting machine arrive and the binder is kept going all next day. In our silo filling circle the man on whose farm we are working supplies the horses and the driver for the binder. While we consider it advisable to be well ahead with the cutting there is always the danger of getting too much corn down. In case of wet and consequently muddy weather men don't like to go into the fields with their teams or to handle the muddy bundles of corn. And yet if the corn is to be gotten into the silo in the best condition it must be put in soon after being cut. One little point I would note here. Occasionally due to very unfavorable weather it is impossible to get the corn planted until very late in the season. When silo filling time comes around the corn has altogether too large a water content to go into the silo immediately after cutting. I would cut such corn and allow it to lie a while to dry out.

SHARP KNIVES NEEDED.—The point in the management of the cutting box on which I would lay most importance is in keeping the knives sharp. This reduces the amount of power required and the machine is able to make a clean cut at every revolution. The knives should be sharp enough to cut the husks of the ears. When the knives begin to get dull the husks will be blown up uncut although the ears and stalks will be cut all right. I mentioned that we have two men apportioned to feed the cutting box. It is hard active work to feed fast and properly, too hard for one man to stand for any length of time. According to our system the two men take turn about at the feeding, and while one is doing the main work the other gathers up the loose stalks and trash and feeds it into the cutter, and with the help of a boy to turn the grindstone or some kind of power to do it keeps the knives sharp. Another point in the cutting is to have a good powerful engine. With insufficient power the blower will be continually choking, and it is poor economy to have several teams and a big bunch of men standing idle while a clogged blower tube is being cleared or repairs are being made. The customary length for cutting the corn stalks is about half an inch and this is about right. If cut in longer lengths the mass of corn cannot be tramped so compactly, the air is not excluded as well and the corn will not keep as long. As a gen-

eral rule we feed the cornstalks to the silage cutter tassel end first. The only exception to this rule is when the men in the field make a mistake and load the wagon the wrong way.

FILLING.—The place where we put the best man in the outfit is in the silo. One good active man can usually handle the distribution and packing of the silage properly, but he must be good and active, otherwise another man is put in to help handle this end of the filling. We have a distributor fixed at the end of the blower tube. With this distributor the silage can be directed to any part of the silo. With the best distributor, however, there is a tendency for the heavier portions of the corn to pile up together while the lighter portions are blown to one side. Were this corn not forked over properly and mixed the silage would be of uneven quality and would settle unevenly. The way we do things in our circle each man's corn is all cut and put in the silo at the one operation. We never go to the same farm twice in the season. As all who have silos know, however, the silage will settle several feet after the first filling and that much storage capacity is wasted. Where one has twin silos this difficulty may be overcome to a certain extent by shifting the blower back to the first silo after the second one has been filled. Most of us, however, myself among the number, have only one silo. I have gotten around the difficulty by building a cheap wooden top on my cement silo, extending to a height of six feet above the cement. This top is cheaply constructed without any attempt to make it airtight. The corn is filled in right to the top of the superstructure, and in a few days it has settled down within the bounds of the cement silo. To prevent the surface of the silage from decaying I soak the corn with a solution of common salt and water, almost concentrated. Following this method there is practically no decay.

STAVE SILOS.—I have had no experience with the stave silo, but some of my neighbors have and consider them very satisfactory. One point on which they lay great stress is in watching the silo carefully after it has been filled. Silage is apt to heat or sweat and thus expand the staves. Unless the hoops are loosened slightly at this time they may burst. Particular attention should be given to the hoops at the bottom of the silo. I like the cement silo mighty well and will build another one this Fall. The main point I would emphasize about our silo filling plans is the co-operative methods of supplying the labor. It is best not to change around among different neighbors each year. Work in gronps year after year and the work will go much more smoothly.

Illinois. H. U. W.

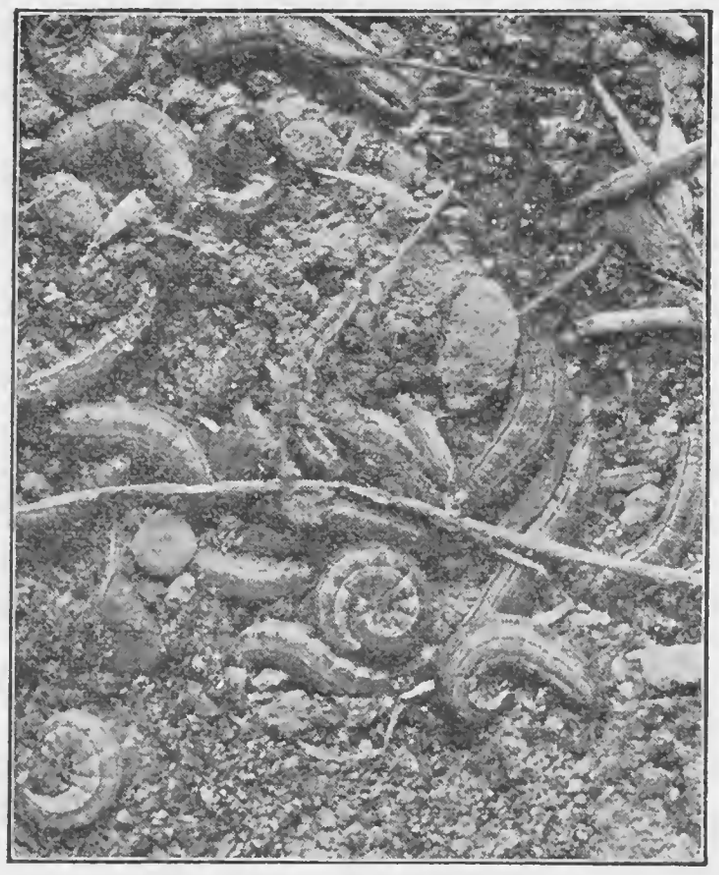
BIG STORIES WHITTLED DOWN.

WHAT is there in the raising of Dahlias? Is all true that is told in the *Country Gentleman* of recent date? Seems to me if it were every one would be in it. H. N. F.

The possibilities of making easy money in a short time, and apparently unlimited quantities, were outlined in the *Country Gentleman* in a recent issue by Maurice Fuld, who advises farmers very strongly to plant Cannas, Gladioli, Dahlias, etc., by the acre, and watch them grow into money so fast that in one instance he dare not compute the acre value of the crop. Too bad he did not figure this out, as the figures he does give are interesting, as they range in returns from $5,000 per acre to $10,000 on Gladioli, and $5,000 to $6,000 per acre on Dahlias. We find the kernel of the nut in this statement: "In all these instances the purchasing of the initial stock is practically the total investment necessary, for all these varieties increase rapidly. Occasionally there are additional expenses for labor and fertilizer."

Mr. Fuld is interested in a company supplying the initial stock. Take Gladioli as an instance. It is advised to plant 250,000 per acre. Figure this out and compute how much hand weeding would be necessary, and any farmer knows that occasional labor bill is not going to be a small item, as they must be planted first thing in Spring and kept free from weeds till frost. It is possible to sell the cut blooms for $20 per 1,000 and sometimes more, but last season many of the variety America shipped from here did not bring as much as the bulbs cost, and we sold through our regular merchants, who have a large trade and are able to dispose of flowers when the farmer, who is not a regular shipper, would probably not be able to dispose of any, unless by working up a trade in a nearby town or village, and even this would likely prove difficult, as most small town residents have gardens of their own and do not purchase many flowers.

Mention is also made of each large bulb having 25 or more small ones that attain marketable size rapidly and are ready for sale third season. In our soil very few of these small bulbs ever mature. Another quotation follows: "The lowest wholesale price quoted on this variety (America) to-day is $20 per 1,000 bulbs, so that the root crop alone is worth $5,000 per acre." This leaves the reader



ARMY WORM ON OAT STUBBLE. Fig. 448.

under the impression that you buy a bulb in Spring, plant it, grow a flower and sell it, and later have a bulb to sell at what you paid for the bulb in Spring. The old root makes one large corm ready to dig just before frost, which you must store for next season's planting, so you have no bulbs to sell the first season nor the second, unless you are fortunate in getting a good growth from the small cluster of cormels attached to each large one; but these small cormels require two seasons' growth and attention before they will flower, and the past Winter salesmen from Holland were travelling the country over selling America at just a trifle over half the figure Mr. Fuld states as the lowest wholesale price. Suppose an individual farmer had a few thousand surplus bulbs to sell. Would not the expense of selling in the face of this strong foreign competition add quite an item to the expense of growing?

The Dahlia is another flower held out as a veritable Aladdin's lamp, that only needs to be planted and the genie will bring us fabulous riches. In locations where the soil is warm and sandy the Dahlia grows very well, and is a crop that gives a fair

ARMY WORM ON CORNSTALK. Fig. 449.

return for the money and labor invested. There are large quantities grown in southern New Jersey and shipped from there in large quantities to the large cities each season. Where the soil is heavy and of a clay nature the newer and expensive varieties make very few flowers. The plants are subject to leaf spot disease, and in a dry season nearly all leaves fall off. The tarnished plant-bug also punctures the heads, which checks the growth, causing a lot of short stems to start out so late that the flowers do not mature before frost. Some of these troubles could probably be overcome by spraying and irrigating, but the tarnished plant-bug apparently cannot be successfully combated. Some commercial growers here have only the small increase of bulbs or roots to offset their investment and have quit the business, as our soil is heavy and the Dahlia will not bloom enough to pay for work put on same. The market for Dahlias in the large cities after the first few weeks becomes very badly glutted, and many thousands that are shipped in do not find a purchaser.

It is unfortunate indeed that such roseate visions of easily earned wealth are apparently endorsed by one of our widely circulated horticultural papers, as everyone who tills the soil knows there is no crop that we can put in the ground that does not require constant care and attention.

Lancaster Co., Pa. ELMER J. WEAVER.

VERBAL CONTRACT FOR LIME.

A BURNS and sells lime. B has an orchard of four acres in a good sod, using the mulch system. A comes to B in November, 1913, to see if he can sell B some lime. B tells A if he could get some one to plow and fit the ground for seeding in the Spring for oats and grass he would buy some lime. A agrees to do all the work at a given price per day, and to deliver the lime at a certain price per ton. B tells A to go ahead and do the work, feeling satisfied that A would do as he agreed. A plows B's orchard in December, 1913, and delivers the lime in January, 1914, and lets it lie for slaking three weeks. B goes to A and requests A to distribute the lime and harrow the land, as B has told A he wanted it harrowed three times before seeding. A tells B there is plenty of time and to be in no hurry. B requests A at four different times to complete the job. Finally, A tells B that he is unable to finish the job, claiming short of help and horses in foal, and advises B to get others to complete work, which B did without success. A sends his bill for lime and B refuses to pay before A completes his agreement (plowing had been paid for). A sues B for lime. B enters an offset claim for damages, for loss of oat crop and bad condition of land being left in open furrows since December, 1913, up to date. A gets judgment against B for price of lime. B's offset claim is set aside. Amount involved $28. Would you have appealed in such a case? I have paid it. J. M. V.

This is another instance where the rights of the parties could better have been preserved by a written contract instead of a verbal agreement. By no means are all written contracts void of ambignity, but where the intentions of the parties are written down and agreed upon between them, there is less danger later of a misunderstanding. In your case A's version of the contract was interpreted by the court as the true one, and he was given the judgment, and we think you did the wise thing in not appealing the case. It seems to be a case of an interpretation of the terms of the agreement between A and B, and without any writing to help the court must do its best in finding out what that agreement was.

M. D.

NOVA SCOTIA APPLE FIGURES.

IN addition to keeping records of individual tree yields, it is useful to know how different varieties of apples are affected when frost has cut down the general crop. Nova Scotia in 1909 had about 700,000 barrels; (frost) 1910, 400,000 barrels; 1911, 1,500,000 barrels; 1912, 750,000 barrels; (frost) 1913, 450,000 barrels. My yearly crops of certain varieties were:

Year.	Spy.	Gravenstein.	Stark.	King.	Baldwin.	Ben Davis.
1908	36	147	114	114	52	126
1909	57	119	147	168	64	131
1910	65	99	99	26	49	98
1911	77	240	205	207	88	229
1912	107	403	403	175	82	257
1913	55	79	97	125	76	150
Total	397	1087	1065	815	411	991
Taking the year 1911 as 100%	85%	75%	85%	65%	77%	71%

The percentage of fruit for each year on same basis runs:

Year.	Spy.	Gravenstein.	Stark.	King.	Baldwin.	Ben Davis.
1908	46%	61%	55%	55%	59%	55%
1909	74	49	71	81	72	57
1910 (frost)	84	41	48	12	55	42
1911	100	100	100	100	100	100
1912	138	167	196	84	93	112
1913 (frost)	71	32	47	60	86	65
Average yearly set	85%	75%	86%	65%	77%	71%

The only feature which may occasion a little trouble is that the 196 barrels of Stark in 1912 included about 20 to 30 barrels off young trees. The soil is light, sandy loam.

The United Fruit Company, Ltd., of Nova Scotia, is sending a special sales agent to South America.

Nova Scotia. JOHN BUCHANAN.

THE NEED OF POTASH FERTILIZER.

Rendering Insoluble Compounds Available.

THE heavier soils of the Eastern States, like those of the Middle West and the farther West, contain very large proportions of potash. The red shale soils of New Jersey and Pennsylvania usually contain more than 1½ per cent. of total potash and often as much as two or even 2½ per cent. of this constituent. The slate and silt loam soils of the East and the Middle West seldom contain less than 1½ per cent. of total potash. In view of this fact, and in view of the fact, also, that the subsoils are even richer in potash than the corresponding surface soils, there is really no danger of exhausting the supply of potash in our heavier soils in many centuries. It happens, however, that, notwithstanding this large proportion of potash in our heavier soils, the amounts that become available from day to day during the growing season may not be sufficient to provide for the needs of maximum crops. This applies particularly to conditions where intensive methods of farming are followed, and where certain potash-loving crops, like potatoes, tobacco and sugar beets, are produced. In order, therefore, to provide for the needs also of the crops grown under intensive conditions, it becomes necessary either to stimulate the chemical and biological changes in the soil which serve to liberate large amounts of available potash, or to add directly quantities of soluble potash salts as is done by progressive farmers who use potassic fertilizers.

It is legitimate, and even desirable, for progressive farmers to utilize the large stores of potash present in our heavier soils, provided this can be done economically. The use of lime and the maintaining of a large proportion of readily decomposable vegetable and animal matter in the soil may provide quite fully for supplying the maximum needs of the growing crops for potash under any given climatic conditions. Hence, the shutting off of the supply of potash salts from Germany may compel the American farmer to utilize in a larger measure than he is now utilizing the potash resources of his own soil. Should it become impossible to purchase potash salts at any reasonable price, it will be necessary for those farming our heavier soils to use larger amounts of lime, and to utilize to a far greater extent than is now being done crops like clover, vetches, Soy beans and cow peas as green manures. There is no doubt that the quality or quantity of our crops grown on the heavier soils will not depreciate under these conditions for at least a year or two even though no potash salts be applied for that length of time.

THE MODERN WAY OF CUTTING CORN IN ILLINOIS. FIG. 450.

There are other ways in which the enormous stores of inert potash compounds in our heavier lands may be utilized to advantage. It is well known that sodium salts, like common table salt, known as sodium chloride, or another sodium salt known as sodium sulphate, which is a by-product and can be had at a reasonable cost, can be used as indirect potash manures. These soluble sodium compounds, when applied in any considerable quantity, will react on the insoluble potash compounds in the soil and will render them available to a marked extent. Hence, should we be driven to get along without the potash fertilizers derived from German mines, we may legitimately utilize our soil potash by rendering them available through the use of sodium salts.

The problem of maintaining an adequate supply of potash on the lighter soils is a more difficult one to solve. Sandy loams may contain as much as 1 per cent. of total potash; sandy soils of the poorer grades not infrequently contain only ½ per cent. of this constituent. Hence, the using up of the soil potash by means of lime, green manures and sodium salts cannot be carried on as far nor as successfully. Nevertheless, even in the case of these soils, especially where potash fertilizers have been used for a number of years, there is a possibility of producing maximum crops for at least one or two seasons without the addition of soluble potash fertilizers. Some of the asparagus growers on the lighter soils of New Jersey appreciate the value of common salt as an aid in the growing of asparagus. The value of common salt has also been recognized by the growers of mangels and of other root crops. If forced to it, we can manage to maintain maximum production even on the lighter soils of the Coastal Plain without the use of potash salts. Beyond one or two seasons, however, it is doubtful whether maximum production will be attainable without applications of available potash compounds. Should this emergency arise, we shall find a way to utilize the vast stores of potash found in certain of our rocks. Indeed, several chemical processes are now available for making available potash fertilizers out of feldspar. These processes have not found, thus far, commercial application because of the difficulty, or even impossibility, of competing with the product of the German mines at existing prices, but, should the war shut off the supply from these mines, American chemists and manufacturers will find a way to make available large quantities of potash from home sources at a relatively reasonable cost.

Everything considered, no alarm need be felt by the American farmers as to any possible potash famine and the falling off of crop yields because of the temporary discontinuance of potash shipments from Germany. Meanwhile, it would be well for American farmers, especially those who use large quantities of potash in mixed fertilizers, to reduce the proportion of this ingredient, or to utilize in so far as may be possible lime and green manures so as to eliminate temporarily the need for potash fertilizers.

Director N. J. Exp. Station. J. G. LIPMAN.

THE ARMY WORM.

PART II.

LIFE OF AN ARMY WORM.—Like other insects of its class, the army worm has a life cycle consisting of four distinct stages, viz.: egg, caterpillar, chrysalis, and adult. The army worm, then, hatches from an egg, feeds about four weeks or until fully grown, then changes to a chrysalis, from which, two weeks later, the moth emerges. The Winter is passed by the half-grown caterpillar, which continues to feed in the Spring, becoming mature in May and forming its chrysalis or pupa in a cell in the ground. The moth comes forth about two weeks later, mates and the female lays upwards of 700 eggs on blades of grass. From eight to 10 days are required for the eggs to hatch, and it is this brood of caterpillars which cause most of the damage. In Connecticut this year, most of the caterpillars had transformed to the chrysalis stage by August 1. The moths emerging this month will lay eggs for another brood of caterpillars, which will appear in September.

DESCRIPTION.—The egg is less than a millimeter in diameter, nearly spherical, almost smooth, but marked with fine ridges, and white or pale yellow. Eggs are laid in rows in the unfolded sheath of the leaf-blade, and are covered with a transparent gelatinous substance. The caterpillars molt five times, and when about full-grown, they are from one to one and one-half inches in length, generally brown in color (though varying greatly) and usually showing tints of green or red; they are darker above than beneath, and are marked longitudinally with fine lines of white, yellow, or lighter brown. A broader yellow stripe runs along each side, and includes the spiracles or breathing pores. The chrysalis is a naked pupa nearly three-quarters of an inch in length and of a light reddish-brown color. The female moth has a wing-spread of about one and three-fourths inches. Fore wings are light brown, more or less mottled, with a white dot just beyond the center of each, and with a dark streak nearly bi-secting the apical angle. The rear wings are usually lighter in color at the base and darker on the outer margin, than the fore wings. The male is smaller, of a lighter brown color, and uniform on fore and rear wings, without prominent markings. All but the egg stage were shown on page 1027.

NATURAL ENEMIES.—All domestic fowls and many other kinds of birds will eat army worms. Blackbirds, starlings, robins, thrushes, catbirds, barn swallows and even English sparrows have been observed devouring them. Among other vertebrate animals, hogs, skunks, frogs and toads feed upon them. Certain predaceous insects like ground beetles and soldier bugs destroy army worms, but it is upon the parasitic insects that we must depend to keep them down. A two-winged Tachinid fly, Winthemia quadripustulata Fabr., and another closely related species, are among the most important of these. Their white, oval eggs, are found fastened to the backs of the army worms, usually near the head, as shown on page 1027. In one Connecticut field this Summer, 40 per cent. of the caterpillars gathered at random, had these eggs on their backs. Several species of small four-winged flies, are parasites of army worms, and in the grain fields this season, their clusters of woolly cocoons (the species not yet identified) were found in great numbers under the cocks and windrows. A bacterial disease called "wilt" also kills many of the caterpillars, which we find dead and shriveled, hanging to the stalks.

CONTROL MEASURES. — Local conditions must be considered in adopting control measures, several of which are recommended. Some will fit one place, some another, and often various combinations of two or more of them must be used to bring about the best results. Some of these methods follow: In small infestations near the house, the hens, turkeys, ducks and geese may be utilized to eat the worms. Small areas in the field, and especially lawns, may be gone over with a heavy roller to crush the caterpillars. Army worms, like cutworms, will eat bran mash, if placed upon the ground. To 25 pounds of wheat bran add one pound of dry lead arsenate or Paris green, and thoroughly mix; then add two quarts of cheap molasses, and enough water to make a fairly stiff mash which can be poured upon the ground. This method is well adapted to prevent damage in the vegetable garden and around the edges of the corn field, but, of course, poultry must be kept away from it.

SPRAYING AND POISON BARRIERS.—Strips of grass, grain, or corn may be sprayed with lead arsenate (six pounds of the paste in 50 gallons of water) to check the advance of the on-coming worms. Uninfested fields may thus be protected, if surrounded by such a strip of poisoned vegetation. We can often take advantage of existing walls, highways and ditches, to check the advancing army of worms, and concentrate our efforts toward their destruction at these points. We can also plow deep furrows across their line of march, or around fields to be protected. In such cases the furrow should be at

(*Concluded on Next Page.*)

THE ARMY WORM.

(*Continued from page 1047.*)

least six inches deep, with the perpendicular or land side straight and clean, and away from the worms or next the crop to be protected. Deep holes 10 or 15 feet apart in the bottom of the furrow will often help, because the worms in their attempts to get out will crawl along the furrow and collect in the holes. As with all other barriers, this furrow is not a permanent bar, but a temporary check, and we can easily kill the worms in it by crushing, by sprinkling with kerosene, or by covering with hay or straw and burning. In certain cases a log drawn back and forth in the furrow was found to be an excellent method of crushing the caterpillars. One Connecticut Yankee this year saved his corn by plowing a furrow around it, and spreading a layer of poisoned bran mash in the bottom of the furrow. It has been noticed that the worms will not cross a road which has just been treated with asphaltum oil. They can often be deflected from their line of march by sprinkling kerosene along the ground; but it is usually advisable to put the kerosene on the caterpillars if you can get at them.

CULTURAL METHODS.—Fall plowing is usually advisable for the control of army worms. Even immediate plowing and thorough harrowing of badly infested fields, will destroy many worms and chrysalids by crushing, and by bringing them to the surface where birds can eat them. Grain, if ready to cut when the worms first attack it, may be saved by promptly reaping, binding and carting it to a field not infested, to be cured. As soon as it has partially dried, the worms will not eat the leaves or pedicels.

FUTURE PROSPECTS.—Seldom, if ever, does the army worm cause serious damage for two consecutive seasons, in the same locality. There will be another brood of worms this Fall, which may cause some injury to rowen, rye, or late vegetables in some localities. But the very severe parasitism leads us to believe, that in Connecticut, at least, there will be only slight damage from the next brood, and that it will be difficult to find any army worms next season.

Conn. Exp. Sta. W. E. BRITTON.

THE WAR AND COMMERCE.

THE movement of shipping to British and French ports has increased materially during the week, nearly 1,000,000 bushels of wheat having been sent from Galveston, and 3,600,000 bushels of wheat and 75,000 barrels of flour from other ports. Grain speculators have again been active, buying back the holdings they sold when shipping stopped. Wheat prices are erratic, up five cents per bushel one day and down the next, as the speculative hysteria chances to run. Oats and corn are three to five cents higher, corn mainly because of drought, and oats on account of sales for war purposes. Flour has made further advances of 25 to 35 cents per barrel on practically all grades, the jobbing price on carlots of patent from city mills being $6.85.

Sugar has made a net advance of three cents per pound since the war began, granulated now wholesaling at $7 to $7.50 per 100 pounds. The Continent of Europe usually produces about 4,000,000 tons of beet sugar. The cane sugar crop of the West Indies and Hawaiian Islands is reported large, five shiploads being now on the way from Atlantic ports via the Panama canal.

The cotton export trade is looking a trifle better. Europe is expected to take 3,000,000 bales less than normally, but will doubtless use much more of our manufactured goods. Japan will probably take 2,000,000 bales of our raw cotton, as they are working actively to supply the extensive cotton cloth trade of China.

The advance on meats previously reported has been only partially held. Public sentiment quickly gets after rises in meat prices, believing that they are usually manipulated rather than necessary, and so much less meat is used that the dealers notice the lessened trade at once. There is no doubt, however, that all meat products will remain on a higher basis if the war continues for several months.

Some of the tied-up German merchant ships now in New York harbor are supposed to be for sale. If this country buys them, as now seems probable, our commerce will be greatly increased, particularly with South America, a promising field that we have not been able to do much with because of having no merchant marine. Even though the seas may be fairly clear and ships running regularly to Europe, exports will not be normal so long as the war hangs in the balance, as at present, as there is too much delay and uncertainty about financing the shipments. War is a world habit. It would be difficult to find in historic times any 50-year period without some war that could be called great, to which business has to adjust itself, yet the conditions vary so widely that the industrial adjustments of one war are not adapted to the next.

COMING FARMERS' MEETINGS.

National Paving Brick Manufacturers' Association, eleventh annual convention and paving conference Buffalo, N. Y., September 9, 10, 11, 1914. Secretary, Will P. Blair, 832 B. of L. E. Bldg., Cleveland, Ohio.

National Dairy Show, Chicago, Ill., October 22-31. The following meetings and conventions will be held in connection with the show: American Association Creamery Butter Manufacturers, Oct. 26. Holstein-Friesian Association of America, Oct. 26. International Milk Dealers' Association, Oct. 26 and 27. Conference, Secretaries of State Dairymen's Association, Oct. 27. Official Dairy Instructors' Association, Oct. 27. National Dairy Union, Oct. 28. American Dairy Farmers' Association, Oct. 28. Council of the National Dairy Show, Oct. 28. National Association of Creamery Managers and Owners, Oct. 28. American Jersey Cattle Club, Oct. 28. National Association of Ice Cream Manufacturers, Oct. 28, 29 and 30. International Association of Dairy and Milk Inspectors, Oct. 29. American Guernsey Cattle Club, Oct. 29. Congress of Marketing, Oct. 29. Milk Producers' Association, Oct. 30.

New England Fruit Show, in connection with the Rhode Island Fruit Growers' Association annual meeting, in Providence, R. I., November 9, 10, 11 and 12; secretary, A. M. Parmelee, Norwood, R. I.

National Grange, annual meeting, Wilmington, Del., November 11-14.

Maryland Week Exhibition, State Horticultural Society, Maryland Crop Improvement, Dairymen's and Beekeepers' Associations, Baltimore, November 16-21.

Annual Show of the Paterson, N. J., Poultry, Pigeon and Pet Stock Association, November 18-21.

Indiana Apple Show, Tomlinson Hall, Indianapolis, Ind., November 18-24.

Western Connecticut Poultry Association of Danbury, Conn., Inc., nineteenth annual exhibition, Hull's Armory Hall, Danbury, Nov. 26, 27, 28; secretary, Thomas Deans, 39 Hoyt St., Danbury, Conn.

Hillsdale County was visited with splendid rains the week of August 10, and much good has resulted to pastures. Corn was helped, but much of the corn was too far gone to be saved and some had already been cut for fodder. Late potatoes are little hurt by drought. Butter and eggs have risen some two cents in the past week. Some wheat is being held by the farmers and town people are feeling the high war prices when buying chicken feed. Shelled corn sells at 90, wheat at $1, prepared scratch feeds $2.25 a hundred. Poultry is good and quite plentiful, about 10% more being raised in southern Michigan and northern Indiana than last year. P. L. W.

Michigan.

PHOSPHORUS

Is the limiting element in crop production on 90% of the soils in the Middle and Eastern States.

ROCK POHSPHATE

has been proven to be the only economical and permanent source of Phosphorus by 18 years of experiments by the Experiment Stations of these States and by its increasing use by thousands of practical farmers.

Let us show you how you can secure increased wheat yields at less than 10c per bushel by using

DAYBREAK ROCK PHOSPHATE

FEDERAL CHEMICAL CO.

THRESHERS
HORSE POWERS
SAW MACHINES
ENSILAGE CUTTERS
GASOLINE ENGINES

Don't buy any of the above till you get our Catalog and reasonable prices. We'll surprise you. Hundreds testify to the wisdom of this counsel. Send for new 1914 Catalog full of pictures. A. W. GRAY'S SONS, 14 South Street, Middletown Springs, Vt.

Wheat or Straw?

On some of the best wheat land the crop runs to straw. This is because there are not enough available mineral foods to balance the manure or clover.

A field test on such land showed that Potash increased the grain from 20 bushels on unfertilized soil to 31 bushels where

POTASH

was used, and to 37 bushels where Potash and phosphate were used. Both were profitable. Supplement the humus of such land with 200 lbs. acid phosphate and 30 lbs. Muriate of Potash or 125 lbs. Kainit per acre. **Potash Pays.**

If your dealer does not sell Potash, write us for prices, stating quantities required, and ask for our free book on "Fall Fertilizers." Study of the fertilizer question means saving and profit to you.

Saving Seed Beans.

WILL you tell me how to handle green snap beans to save them for seed? What treatment is given them to prevent weevil infesting them? I have an acre of fine beans just ready to pick; early drought delayed them. New York market is now 25 cents per bushel. I think I can get some value as seed. What do you suggest? I have never saved any for seed before. F. C.
Vineland, N. J.

Gather the pods when nearly ripe, or in other words, before they become thoroughly dried on the vines. Dry them well in the shade of some outbuilding, and bag them in the pod. Do not shell them until they are wanted for use. Corn, peas and beans will not suffer much from the attack of weevil if nature's covering is not removed, but if this cover of protection is removed, the weevil will quite often destroy the whole crop. This is particularly true in the Southern States and in some sections of the North. In the South, corn is always cribbed with the shuck on, and thus escapes the weevil's attack for quite a long time, whereas if it was shucked before cribbing the grain would probably be entirely destroyed before Spring. I have kept beans and peas in the pod for two years or more, without being attacked by weevil. Good clean bean seed should not be difficult to dispose of to seed dealers at a fair price, but before gathering the crop, I would advise that you write some of the reliable seed firms and find out what they will be willing to pay for a first-grade article. You will then get an idea if it will pay you to harvest the crop for seed purposes. K.

Slitting the Bark for Blight.

TWO years ago I had a Yellow Transparent tree that was badly affected with twig blight. All dead wood was trimmed out carefully, but last Summer it was worse than ever. While visiting a friend's orchard I noticed long slits down the bark of all trees of this variety and he explained them by saying it was a preventive for blight. I laughed at him, and he said he had laughed too when told about it. My tree looked so bad last July that I gave it a few slashes and then gave it some more for good measure. No blight this year, and a lot of new wood is ripening up nicely at the present time, and we have picked three baskets of the most beautiful fruit I ever saw of this variety. It does not seem possible that this cutting did the work, but something did, for other trees are showing as much blight as last year. Is it a freak of nature that both my friend and I should hit the off year in blight on trees, or is it possible that young trees are benefited by the treatment? WALTER C. BLACK.
New Jersey.

R. N.-Y.—We will turn this over to the wise men for a discussion!

School Health Law.

IS it the law that a school trustee shall oblige each child to be vaccinated before he can come to school? Many parents do not want their children vaccinated, and I wish to know if it is law. We had a doctor examine school last Fall; he charged ten dollars and I do not see where it did any good. We had the school closed last Winter by health doctors; we had to pay teacher for time closed, also for time to be made up. Is that law? W. H. B.
Saratoga Co., N. Y.

The law in New York State has required the vaccination of all children previous to their admission to the public schools since 1893. Until recently this law has been permitted to become very much a dead letter but, owing, doubtless, to the general prevalence of smallpox of a mild form in recent years, this law is now being enforced with some vigor, and trustees or other school authorities upon whom the duty of seeing that the law is enforced has been placed are giving the matter their attention. The law has repeatedly been held constitutional and the school authorities have no option in the matter; the only way in which the law can be evaded by those opposed to it is by sending their children to private schools where they will obtain the instruction made compulsory by the State education laws and where they will not be subject to the compulsory vaccination law.

My opinion is that a public school teacher is legally entitled to pay for his services during the time that his school is closed by the health authorities even though these services are not rendered by reason of the action of the health authorities. Not having looked up the law on this matter I give this as opinion only based upon general knowledge of the health laws. M. B. D.

Destroying Cockroaches in Grain Bin.

HOW may cockroaches in a grain bin be exterminated? A. P.
Oswego, N. Y.

Any insects in stored grain may be destroyed with bisulphide of carbon. The allowance is one pound of the liquid to each 100 cubic feet of space, or if grain is being fumigated, one pound to 100 bushels; in small quantities about two drams to the bushel. The bisulphide is exposed in shallow dishes, on top of the material to be fumigated; the bin is then tightly closed, preferably with a canvas or blanket thrown over the top, and then left for 24 hours. Always remember that the bisulphide is highly inflammable and explosive; no light, fire, cigar or pipe must be allowed near it until all fumes have passed away. The liquid evaporates rapidly on exposure to air, giving off a heavy gas which floats downward, as it is heavier than air. There is no danger if proper care is taken, but where there is risk of fire another chemical, carbon tetrachloride, is advised, as this is non-explosive. It is less active than the bisulphide, and double the quantity must be used.

THE MAIL BAG.

Legal Bushel of Walnuts.

IS there any legal weight for a bushel of black walnuts? If not, are they sold by a standard weight, or in bulk? They are always quoted "bushel," no weight mentioned, as with shagbarks.
Willimantic, Conn. J. H. W.

There may be legal weights per bushel in some States for the wild or Black walnuts, but as they are usually sold by the bushel and there is no very large quantities handled it is not deemed a matter of much consequence. Their actual weight is 40 pounds per bushel. H. E. V. D.

Spraying Trees Against Sheep.

WHAT spray can I use on my young peach and apple trees, so as to prevent sheep from browsing on foliage? The trees are only a year old, and I do not want to wire them in. It has occurred to me that from your experience you may have learned of some application that could be made to the tree, which would be offensive to sheep.
Easton, Pa. G. F. C.

We have never heard of such a scheme being successfully worked out. There have been calls for a wash to spray on dormant trees to repel deer and vermin, but we have found nothing practical. A spray for trees in full foliage would be too weak to have much repelling power. We doubt if the scheme is practical.

Alfalfa in Minnesota.

PUSH Alfalfa. Any location that grows Sweet clover will grow Alfalfa. This is a limestone country, no inoculation of soil. I could have cut my first crop last of May, but continuous rains held us back until first week in July. Now the new growth is 18 inches high, will cut it next week. Seed was sown two years this month, Grimm variety. I have five acres, last year we cut 12 big loads June 10, 15, July 9. They were hindered by rains until September, three cuttings. First cutting this year 20 big loads, delayed cuttings causes lower leaves to drop.
Mankato, Minn. W. M. S.

We think this Alfalfa pushing has come to the point where fair discrimination should be used. A wonderful plant where conditions suit it. There are some cases where it will cost too much to change or fit the soil properly. In such cases Red clover or Soy beans will pay better. Everyone should make a fair effort to grow Alfalfa without plunging too heavily on cost.

Permanganate of Potash for Ivy Poisoning.

JULY 4 issue, page 885, E. H. A. asks for reports on the use of permanganate of potash for poison ivy. He may be assured of one grateful appreciation; it affords relief in a few moments, either by rubbing in well, or by two or three applications one after another as soon as dry, and I believe it would relieve hives also, and possibly insect stings. I tried almost everything except dynamite and came near to committing assault and battery upon one physician who told me the only cure was to let it run its course about six days and keep cool and not get overheated. This to farmers in haying time! E. H. A., we have you as a public benefactor, how did you "get next?"
New Jersey. S. FRIEDLANDER.

Drain Heads vs. Tile.

CAN you tell me whether drain heads are a better system of draining wet lands, etc., than the old style of draining, ditching with stone, tiling, etc.
Hamden, Conn. W. J.

The "drain head" is practically a deep well with a system of drains running into it. The theory is that the water runs into this well and then passes off at the bottom, thus relieving the field even when there is no natural surface outlet. In cases where there is a stratum of open porous gravel below the subsoil this plan may work, but on most of our Eastern soils these wells would give just the condition we *do not want*. They would not drain off at the bottom, but would simply hold the water or flood it back into the land. In nine cases out of 10 the old plan of running off the water through tile or stone drains to some natural outlet will pay better on our Eastern soils.

Roughing a Concrete Floor.

I THINK if persons who are troubled with slippery floors will try the following, they will find the method both better and cheaper, and withal more easily applied than other plans. For each stall, say 4x8 feet, procure one quart of cement and two quarts of sharp sand. Mix the cement and sand thoroughly, dry. Now sweep and wash the floor clean, then spread the cement and sand evenly over the stall floor by means of a piece of lath, having a couple of shoe nails projecting about three-eighths inch from one edge. Should the cement and sand run short, drive the nails in a little and beginning at the front always, go over again. After getting an even surface to the floor you proceed to wet it; for this purpose a fine sprinkler is needed. Too much water will displace the sand while wetting. When the cement is well wetted give it a reasonable time to set and it is ready for use. OSAGE.
Fairfax Co., Va.

GREENSBORO PEACH.—I wish the many readers of THE R. N.-Y. in Northern N. J. could see tree of the Greensboro peach which I planted in May, 1911. It is one of the most beautiful sights I have seen this season, and they were ripe enough to use on July 28, earlier than I ever had peaches before, though I have 15 kinds in my orchard. Every house owner should have one or more trees of the Greensboro. A. C. WORTH.

WHEN you write advertisers mention THE R. N.-Y. and you'll get a quick reply and a "square deal." See guarantee editorial page.

Sour Soil

Next to the possession of soil and proper moisture, there is no factor more essential to successful crop cultivation, than the presence of **Lime.** Where lime is absent the soil becomes sour and non-productive—a condition which is speedily and effectively remedied by the use of

Edison

PULVERIZED LIMESTONE
NATURE'S CROP PRODUCER

This excellent lime product is made from the purest Crystalline White Limestone obtainable. Pulverized like flour and not being *caustic* can be applied without danger to plant life. Farm lands greatly increase all crop yields by its use. **Especially recommended for Alfalfa.** Lawns "run down" and of slow growth fully restored and the grasses thickened. ¶This signature guarantees satisfaction and reliability

TRADE MARK
Thomas A Edison

Edison Pulverized Limestone
is packed in 100 lb. bags, also in bulk. Sample and prices furnished on request. **Ask us to send booklet No. 202.** It is instructive and will please you.

EVENTS OF THE WEEK.

DOMESTIC.—The chase after the five bandits at Williamson, W. Va., who on August 14 killed Joseph Shaler, paymaster of the Glen Alum Fuel Company, and his two companions and stole the company payroll of $8,000, ended August 16, when the mountain cave into which the desperadoes had retreated was dynamited and the men were killed. The deaths of the bandits brought the fatalities to eleven. The bandits were Italians.

The United States War Department steamship Ancon made the passage through the Panama Canal, August 15, and transit through the waterway is now officially open to the traffic of the world.

At a meeting of the New York Chamber of Commerce, August 13, a resolution was adopted unanimously to request the United States Government to establish a bureau of war risk insurance to be administered under the direction of the Secretary of the Treasury. This bureau would assume the risks of war on American vessels and American cargoes shipped thereon whenever it shall appear that the American vessels are unable to compete on equal terms with foreign vessels by reason of protection afforded to them by their Governments.

The Dutch steamer Nieuw Amsterdam, and the Cunard steamer Laconia, arrived in New York August 17 with about 3,000 American tourists, while a Scandinavian liner arrived August 18 with 1,000 more. The North German Lloyd Company admits that its vessels are for sale.

Subpoenas were placed August 18 in the hands of United States marshals requiring the presence of ten of the leaders in the Chicago packing industry before the federal grand jury examining into the recent increase in meat prices. The same day Robert O'Dearn, American sugar beet man and A. A. Brown, of the California-Hawaiian Sugar Refining Company, were served with subpoenas at San Francisco, directing them to appear before the federal grand jury which is investigating the rise in price of foods. Managers of hotels will bring their books and bills to show what increased prices they have paid since August 1.

WASHINGTON.—The unusual proposal that the government shall enter the business of marine insurance during the continuation of the European war and the congestion of oversea traffic is contained in a bill introduced August 12 by Representative Lewis, a Maryland Democrat, who came into notice as the co-author of the parcel post law. The Lewis bill proposes the creation in the Department of Commerce of a "Bureau of Marine Insurance," which shall undertake the insurance of vessels carrying exports from the United States to foreign countries. The Secretary of Commerce is to have authority to make rates and regulations, and the premiums received would go into a "marine insurance fund."

Mr. Lewis says that in 1911 the premiums from marine insurance amounted to $4,500,000 and the losses to only $1,500,000. The bill provides that the United States shall have a monopoly of the marine insurance business after the promulgation of its rates covering war risks.

The Senate ratified August 13, eighteen of the peace treaties sent to that body recently by Secretary Bryan. All of the treaties except two were approved and action on these was postponed. The treaties postponed were with Santo Domingo and Panama. Postponement was due to the fact that local conditions exist in each of the two countries which it was thought would make it inconsistent for the United States at this time to conclude treaties of that character with them. The eighteen countries with which peace treaties were to-day confirmed are: Norway, Netherlands, Portugal, Switzerland, Denmark, Italy, Salvador, Guatemala, Honduras, Nicaragua, Bolivia, Persia, Costa Rica, Venezuela, Uruguay, Argentina, Brazil and Chili.

August 13, President Wilson ordered a Federal investigation of the recent abrupt increases in the price of foodstuffs.

Two bills were offered in the House August 18, designed to prevent the exportation of foodstuffs as a means of steadying or reducing the prices of household necessities. One, by Representative Vare of Pennsylvania, authorizes the President to stop the exportation of foodstuffs, clothing and arms and ammunition in time of war. The other, introduced by Representative Keating of Colorado, proposes an amendment to the Constitution whereby Congress may levy a tax on exports.

FARM AND GARDEN.—Albert J. Rice of Dayton was convicted August 13, before Judge Peter F. Daly in the Middlesex County Court at New Brunswick, N. J., of selling millet seed to farmers for A1 clover seed and was sentenced to two months in jail and fined $200. Harvey R. Dey, a farmer, became suspicious of the real character of the A1 clover seed because some new Japan clover seed he had previously bought from Rice had failed to sprout. He sent the seed to the State agricultural experiment station, where it was analyzed and found to be 82 to 92 per cent. millet seed, the balance being clover. Millet seed sells for $1.75 a bushel. Rice asked $10 a bushel for his A1 clover seed.

Pleas of not guilty, with the right to substitute demurrers or different pleas, were entered in the Federal Court at Providence, R. I., August 11, by William J. Higgins and Jeremiah Hall, charged with conspiracy to defraud the Government of $400,000 in oleomargarine taxes. They were held in $15,000 each. The New England Manufacturing Company, of which they are officers, entered a similar plea. Five other individuals and two other corporations have been indicted.

The Smith-Lever Bill which recently passed Congress provides federal funds for the Pennsylvania State College with which to carry on Extension work in agriculture and home economics. The Extension Department of the College will place exhibits at the following fairs: Sept. 7—11, Towanda, Bradford County, and Youngwood, Westmoreland County; Sept. 14—18, Montrose, Susquehanna County, and Mercer, Mercer County; Sept. 21—25, Lewisburg, Union County, and Dayton, Armstrong County; Sept. 28—Oct. 2, Milton, Northumberland County, and Duncanville, Blair County; Oct. 5—9, Bloomsburg, Columbia County, and Bedford, Bedford County; Oct. 12—16, Hughesville, Lycoming County, and Newport, Perry County.

THE EUROPEAN WAR.—All news is still strictly censored. The whereabouts of the British North Sea Fleet was unknown August 21, but as Scandinavian merchantmen were taking cargoes of foodstuffs to England, and English, Belgian and Dutch shipping crossing the Atlantic, it would appear that the main German fleet was unable to prey on shipping. No information was given out as to the whereabouts of British troops in France or Belgium, but it was officially stated August 18, that 140,000 men had been landed on the Continent. During 24 hours, August 19—20, it is stated that 97,000 recruits joined the British army, being the world's record for a single day's enlistments. August 17 Japan sent an ultimatum to the Kaiser, giving Germany one week to withdraw from the Far East. It is officially announced in London that Japan's move against Germany in the Far East was taken with the full knowledge and approval of the British Government, following assurances by Japan that she would abide by the letter of the Anglo-Japanese agreement and that she contemplated no hostile action against any of the German possessions on the Pacific except Kiaochow. Thus the possibility of a Japanese move toward Samoa or other quarters in which the interests of the United States would be affected is eliminated. A copy of the official announcement by the British Government that the operations of Japan will be confined to the China Sea and the mainland of China was handed to Secretary of State Bryan by the Japanese Ambassador in Washington August 18. It had a noticeable effect in relieving uneasiness in official circles. One significant fact in the statement by Japan was that the Tokio Government will insist on being made a party to any negotiations between Germany and China for the return of Kiao-chow to China. The result of five days' fighting between French and German troops in the Vosges Mountains appeared generally favorable to France and the French troops were nearing Strassburg August 18. On that date it was reported that the Germans had retreated from Saarburg. August 18 the Belgian authorities removed the capital to Antwerp, which is protected by forts considered impregnable. Great devastation has been inflicted on towns first occupied and then evacuated by German troops, which occupied Brussels August 20. The two German cruisers in the Mediterranean, the Goeben and Breslau, have been sold to Turkey. All the powers resent this, and the Allies have notified the Ottoman Government that the German officers and crews must be repatriated. These vessels were trapped by Gibraltar and the Dardanelles. It was stated August 17 that Turkish troops were crossing Bulgarian territory to attack Greece. Russia has notified Turkey that if the Black Sea Fleet is not given permission to go through the Dardanelles it will go through without. The Czar of Russia has issued a proclamation offering autonomy to Poland and it is reported that Jews in Russia will soon be given civil and political rights. Reports from Servia August 18 announced that an Austrian army which tried to penetrate the Sabatz Mountaines was routed and 15,000 men killed, wounded or captured. A strong Servian detachment supported by machine guns trapped the Austrians in a mountain valley. The Austrians were unable to form a battle line and retreated in confusion, leaving fourteen cannon. The Austrian army corps withdrawn from the Servian border have assumed the offensive against Russia, and Austrian cavalry has penetrated Russia. A dispatch from Port Said August 18 stated that through traffic in the Suez Canal has practically ceased. The port is crammed with ships of all nations, the captains of which are afraid to proceed on their journeys. Besides, there is a colossal fleet of German merchantmen under seizure that have been deprived of essential pieces of their engines, likewise their wireless installations. The whole of Germany's seaborne commerce with Australia, Asia and East Africa is absolutely paralyzed, and the only vessels passing through the canal are those flying the Italian flag. These are besieged by hordes of foreigners anxious to get away from Egypt, among whom were many German and Austrian officers, who have been arrested by British authorities while attempting, under disguise, to get away.

DEATH OF POPE PIUS X.—August 20 the Pope succumbed to a bronchial attack. Giuseppe Melchiore Sarto was born June 2, 1835, in the small hamlet of Riese, in the province and diocese of Treviso, Venice. His father was a postman, and his early life was among the humble. He was ordained in 1858, became Archbishop of Salzano in 1867, and Bishop of Mantua in 1884; made Cardinal and Patriarch of Venice in 1893, and became Pope in 1903. The last message given out by Pius X was an earnest appeal to pray for peace, and the anxiety over the great war is believed to have hastened his end.

NEW YORK STATE NEWS.

HAY DEALERS CONVENE.—The ninth annual convention of the State Hay Dealers' Association was held in Syracuse last week, with about 300 delegates in attendance. The European war was a dominating subject of discussion and there was a general belief that it would bring a higher level of values for the hay crop although the problem of exporting the crop was a pressing one. Although the crop is a good one and would not denote high prices, yet hay is now worth $12 to $15 per ton despite the abundant yield. Commissioner Huson, in an address before the convention, called attention to the fact that the hay crop in this State average in value more than $75,000,000 per year and constitutes more than 30 per cent. of the value of our farm crops. Among other speakers were Prof. Clyde H. Myers of the State Agricultural College, H. C. Jones of Baltimore and Jacob Ginder of Schenectady.

FINE CATTLE FOR STATE FAIR. There will be 80 exhibitors of cattle this year as against 50 last year and the housing capacity of 1,080 will be exhausted, and more room needed. Two or three stock farms will enter over 50 head each. This year beef animals from the Middle West will be much in evidence.

GRANGE PICNIC.—When every Grange county in the State has its Grange picnic and many subordinate Granges have field days on their own account, no one can be selected for special mention. The Grange day gathering at Chautauqua is one of the most notable and Jefferson County is always wide-awake to the picnic issue. This year more than 1,000 were present at Watertown on the annual Grange field day. State Master Vary, State Secretary Giles and Senator Elon R. Brown were the speakers.

AMENIA FIELD DAY.—This "play festival," as it has been styled, which has attracted much attention, was attended by about 8,000 persons this year on Saturday, Aug. 15. Among the speakers were Prof. J. E. Spingarn, who is the originator of the field day idea as applied to this particular undertaking; Hon. Hamilton Fish, Jr.; Congressman Edmund Platt of Poughkeepsie, Commissioner C. J. Huson, Gilbert M. Tucker and Mrs. Raymond Brown. Athletic events followed the speaking.

KEEPING FOOD PRICES DOWN.—Attorney General Carmody is behind a sweeping prosecution of all combines that tend to boost food prices without cause. Ample power is given him by statute to prosecute all illegal combinations working to this end. For six months an investigation has been going on in his department, in conjunction with the State Department of Health and Federal authorities, and a mass of evidence has been collected bearing directly on the present situation. Gov. Glynn has also directed the State Department of Agriculture "to exert every effort to prevent the abnormal condition of the world's markets from working unnecessary hardships on the consumers of New York." The Commissioner of Weights and Measures of New York City is also carrying on an investigation with the same end in view and it has had a good effect on prices. Acting Mayor McAneny has said that he would favor the plan to have the city appropriate money without delay to establish municipal markets.

CONFERENCE AT KENOTIN FARM.—This farm is owned by Mr. F. W. Sessions of Utica and is a model dairy farm. It was here that an important conference was held last week which was attended by about 175 interested people. Short talks were made by Deputy Commissioner Harry B. Winters of Albany, G. W. Bush of the Oneida County Farm Bureau and Dr. T. Wood Clarke of the committee on milk supply of the Municipal League. The spirit of the speeches was to arouse the public to the pressing need for milk that is known to be pure, by test. Mr. Sessions produces milk that is 100 per cent. pure by analysis made twice a month. It does not fall below that standard. The secret lies in milking from properly cared for cows into covered pails, the rapid straining of milk through cheese cloth and quick cooling to a low temperature. At the conference Mr. Sessions offered his guests milk to drink which, he said, was "four days old." It was as fresh apparently, as when first drawn, and it is said it could be shipped to California and back without spoiling. It is free from bacteria and will keep its purity for a week. J. W. D.

ARMCO—Rust-Resisting Iron

Its Discovery Confirms What the Ancients Guessed

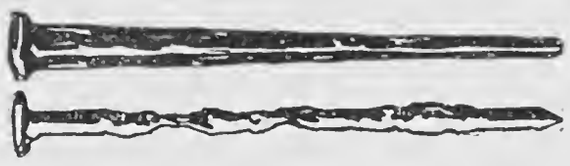
THE rust-resisting qualities of pure iron were ignored for ages. The ancients made pure iron, though they may not have known the great value of it. Thousands of years ago men made tools out of iron. Possibly they used steel, too. But, if they did, the articles have long since gone up in rust. Rust is the great enemy of steel. For many uses where great strength or hardness is required, steel is necessary—but it rusts rapidly. The very things that are mixed into iron to make it steel cause it to crumble away in rust.

The more nearly iron is free from all impurities the greater its rust-resisting power. The iron that has lasted since the Pyramids were built is mighty free from impurities. The pure iron in the sacred pillar at Delhi, India, has stood through twenty-eight centuries of weather.

America furnishes her own instances of the long life of iron. In 1910 an old iron link suspension bridge was torn down at Newburyport, Mass. After a hundred years of exposure the rust on those links was scarcely as thick as a coat of varnish.

But you've seen proof on your own farm of the superiority of iron over steel.

Look at these two nails



The iron nail has seen thirty-eight years of service while the round steel nail is gone with only eleven years' use. You have seen many such comparisons. Did you ever wonder why there is such a difference in their rust-resisting qualities?

We did. And we set to work to find out why most metals rusted, though some did not.

The iron that has lasted we found to be almost pure. But pure iron is hard to make. You add more impurities to already impure iron to make steel. Impurities must be taken out to make pure iron. It never had been done on a profitable commercial basis. The links at Newburyport were from iron purified by crude methods and wrought by hand.

Ideal iron commercialized

Iron made by hand couldn't compete with steel. We knew that. But we were determined to make pure iron. We have done so. And we are continually making more and more. We have commercialized an ideal.

Pure iron is Armco—American Ingot Iron

That is the name of our product. When we first began to make pure iron we called it American Ingot Iron. That name is still widely used. Remember, Armco and American Ingot Iron are the same, mean the same, pure iron. Armco is the purest iron commercially manufactured in the world. Armco Iron is purer in content and more uniform in texture than the iron pillar at Delhi, the links at Newburyport, or the iron nails that served your fathers so well.

Armco Iron is guaranteed to be 99 84/100% pure iron

Not a batch of molten iron leaves our furnaces until chemical tests in our laboratory show 99 84/100% — or higher — purity. American Ingot Iron may be higher than 99 84/100% pure. It is never lower. We guarantee that.

Pure iron roofs last seventy years

You've heard of the good tin roofs that were laid a hundred years ago. Did you know that the core, the sheets that were tinned, was of pure iron? And today you can get the same grade roof—or higher—made of American Ingot Iron.

You can now have pure iron shingles, iron sheet roofings and sidings, metal lath, iron gutters, flashings and drain pipes that will last as long as your buildings.

There's a second reason—in addition to its pure iron base—why American Ingot Iron roofing is better than ordinary sheet metal. The galvanizing on Armco roofs is better.

Steel dissolves in galvanizing much faster than Armco Iron

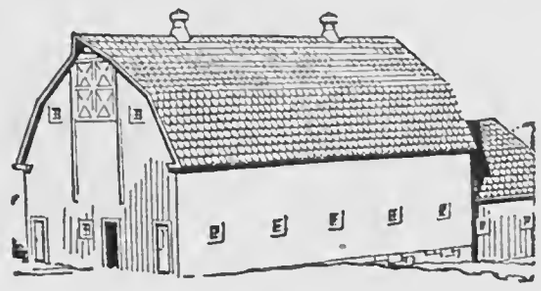
When a sheet of steel is dipped in the galvanizer it begins instantly to dissolve. American Ingot Iron, because of its purity, shows practically no dissolution when the zinc galvanizing is applied. Therefore the zinc coating is purer and will last many times as long as the galvanizing on ordinary, impure material.

Armco Old Style Terne plate, with its Armco Iron base, is made by the Morewood hand dipped, old style, pure palm oil process. Absolutely no acids are used in the process. The coating is pure lead and tin—two almost indestructible metals.

There are seven operations. No higher grade metal roofing is made in the whole world. Each shingle is stamped Armco

Thousands of farmers demand iron roofing

Write for booklet on Armco Iron Roofing

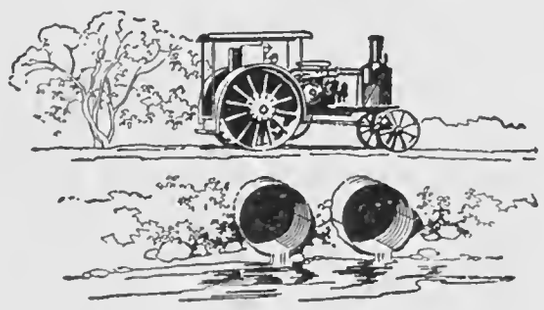


A canvass of farmers showed us the way iron roofing is taking high place among roofings. Out of 8000 farmers using metal roofings 5000 had bought iron. Your metal roof should be Armco—the only 99 84/100% pure iron roof. Every sheet, flat or corrugated, bears the Armco trade mark. Take no other. Write today for Armco Roofing Booklet.

Who pays your road tax?

That's just a suggestive question—a suggestion that you have some right to say what that road tax is spent for. If it's culverts your roads need, here are a few reasons why you should urge your supervisor to install Armco—American Ingot Iron Corrugated Culverts. Their durability is insured by the purity of Armco Iron —its rust-resisting power—and the quality of the galvanizing.

The deep corrugations give strength to

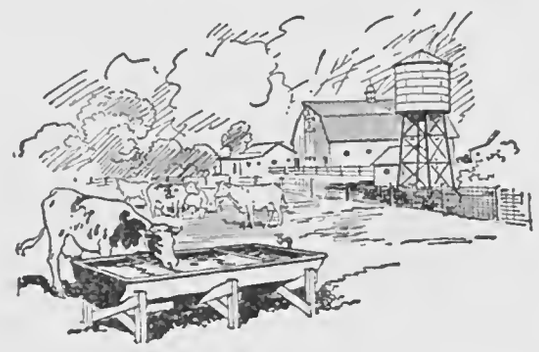


carry the heaviest loads and deepest fills. Armco Culverts have an enormous resistance to external strains. Armco American Ingot Iron Culverts are quickest to install. And because no machinery nor cementing is necessary, they are cheapest to install.

If you need a culvert on your farm we will gladly tell you where you can secure an Armco American Ingot Iron of desired size.

Water tanks need not rust

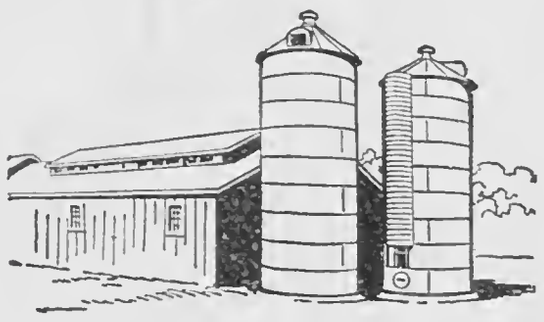
Write for names of tank manufacturers using American Ingot Iron



You can secure storage tanks, pressure tanks or stock watering tanks of Armco Iron. A tank like the one shown here will last as long as its heavy supports of steel. These supports are made of steel so that they will carry the heavy weight. The tank itself should be Armco Iron.

Silos are built of Armco Iron

Write for names of silo manufacturers who use Armco Iron



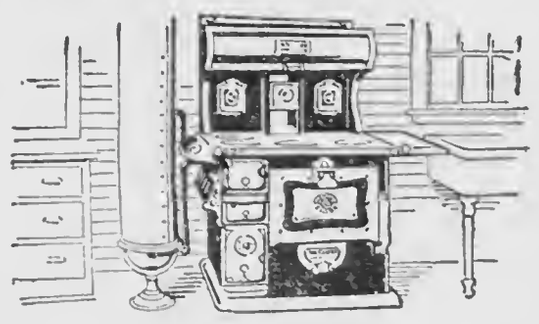
The buildings on a dairy farm can well be made of Armco Iron. The roof on the cow stable, the ventilators, the window frames, and finally the silo can be built of rust-resisting, almost everlasting Armco Iron.

Handsome and durable fencing—Armco Iron Woven Wire Fencing—is made by the Page Woven Wire Fence Company.

Things under shelter rust quickly, too

Write for names of stoves and ranges made from Armco Iron

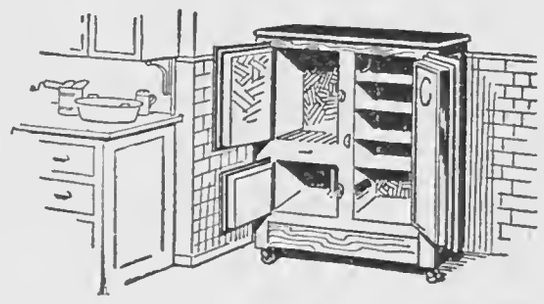
There's the gasoline stove, the water heater, the kitchen range. They rapidly



rust out unless made of pure iron. Alternate heating and cooling hurry the process. The gases of combustion quickly eat into low grade iron and ordinary sheet steel. But Armco Iron resists such attacks. Enthusiastic stove manufacturers, using Armco Iron, guarantee against rust for twenty-five years.

Ice box and furnace can be of Armco Iron

Write for list of furnace and refrigerator manufacturers using American Ingot Iron



Your ice box, especially if it is enameled, should have a base of Armco Iron. Certain manufacturers use it for all enameling purposes. Armco takes a smoother coat, is free from pin holes and bubbles, and—is slow to rust.

And if there's anything that should stand against rust it's a furnace. You can have a furnace with its vital parts made of Armco Iron. We'll tell you the furnace manufacturers who use Armco Iron if your dealer doesn't show you the Armco trade mark on the furnace he tried to sell you.

AMERICAN ARMCO INGOT IRON

You'll find this Armco triangle in blue on all American Ingot Iron sheet roofing, culverts, silos and water tanks. It is your guarantee of iron—rust-resisting iron—99 84/100% pure.

When you see it you are safe in buying the article as being of pure iron. If it isn't marked Armco, ask for proof that the iron used is Armco—the pure iron.

Write for free copy of these illustrated Books!

Every page contains interesting news about one of the most important subjects before you today. By words and by picture, these books tell you the big money-saving facts—the real truth about sheet metal, why you should buy Armco, pure iron.

Fill in your name and address, tell us for what use you are interested in sheet metal, and we will help you.

FOR the benefit of a number of your readers, tell us briefly what were the causes of the war in Europe? It is hard to get it from the daily papers.

INQUIRER.

I wish I knew. I have tried to read history with care, and the history of Germany and France are specially interesting. Yet it seems difficult for Americans really to understand the point of view of most Europeans. The essay on Germany by Tacitus, written over 1800 years ago, shows that even the Romans who conquered the world had a mighty respect for this slow, methodical, obstinate and unimaginative people. On the other hand, books like Watson's "Story of France," make it clear that the French have ever been an emotional, imaginative people. There is evidence of this in the way they have kept alive the feeling regarding Alsace-Lorraine, the two provinces which they lost 43 years ago in the former war. In some way the French people have been able to keep alive the poetry and national sorrow over the loss of these provinces in spite of all the years. Thus, it will be as hard for the busy American to understand the troubles of Europe as it was for the European to understand our politics or public questions. During our Civil War there were Englishmen, thought to be well informed, who insisted that it was a fight between North and South America. They could not understand the idea of a single nation being split apart. I have talked with a number of educated Europeans and asked them *why* the nations are fighting. Many reasons are given as follows:

These are what may be called basic or foundation causes for wars. Our Civil War, for example, was fought over the slavery question, which meant the industrial competition between free and slave labor. The war in Mexico is at the bottom a struggle over the land question.

"THE YELLOW PERIL."—It is said that the Kaiser and a large part of the German people really believe that Europe is in danger of being overrun by Asiatics led by Russia. Personally I know of many worthy men who fully believe this danger is a real one. They claim that the Bible shows this danger. They say our present white races are failing in both physical and moral strength, and unless some powerful man or nation can arise to give battle, the people of Asia will pour into Europe and spread over this country, and dominate civilization for centuries. The Kaiser, according to this theory, believes that he is the man, and that Germany is the nation to prevent this "Yellow Peril."

A RELIGIOUS WAR.—Several Europeans tell me that at heart this war is essentially a conflict over the Greek Church. The people who live in the mountains of Southwestern Europe are dreamers, as all mountaineers are. The Greeks, as a nation, have little except dreams of a glorious past. These people, with the Russians to a less extent, dream of the time when the Greek Church will once more have its headquarters at Constantinople which Mahomet captured in 1453. The ordinary personal dream is made of very flimsy stuff, but when a great religious dream enters the hearts of millions of very stubborn people there is no such thing as changing it. But think how this war has mixed up the nations. There is Protestant Germany tied up to Austria. On the other side are Protestant England, Catholic France and Belgium, Greek Russia and Servia and pagan Japan.

A GRAB FOR TERRITORY.—Another reason given for the war is the German need of colonies and a new outlet to the ocean. Germany has developed wonderfully as a manufacturing nation. Their ideas of development are too large for her territory. She needs new markets and new trade, and therefore must control the sea. She needs colonies abroad, such as England and France have established, and in order to carry out her schemes must have an outlet nearer to the Atlantic Ocean and also on the Mediterranean Sea. Belgium and a slice at the south of France would doubtless suit her well. This would give her a chance at England, a direct shipping port like Antwerp in Belgium, and reduce France to the condition of a second-class nation. On the other hand, England sees how her prosperity and national life would be menaced if Germany reached the North Sea. France realizes that she is no match for Germany alone, but reasons that her only chance of gaining back her lost territory is to unite with England and Russia, when the time is ripe.

SOLDIER OR SOCIALIST.—Napoleon gave Europe a century to become as he put it, "all Cossack or all Republican." What he meant to say was that Russia was the type of brutal autocratic government, and that there could be finally no compromise between that and radical republicanism. It has got to be the autocrat or a self-governed people. Think what a strange mocking of fate it is to now find Russia on the side of the forces which stand against what Napoleon called the "Cossack." For the past few years all Europe has been in a ferment over what we may call the "manhood" question. For many centuries the woman who gave birth to a son was taught to rejoice because she had given a man child to the king to fight or be killed as a soldier. The woman came to think that was practically all she was in the world for! What I call the "manhood" issue is the idea which has slowly grown, from the mere thought which frightened the thinker, that plain, common men and women have higher duties to perform than merely to produce food and raise children to be fed to the cannon and the sword. It is a part of Napoleon's prophesy slowly worked out. It has been helped by the millions of Europeans who have come to this country to work or find homes. Some of these take the money they have earned back to the old country. Others send for their relatives. I know of one big American farm where practically all the workmen come from a village near the Danube River. During the war between Greece and Turkey a shipload of American tourists went through Athens. A regiment of Greek soldiers were lined up to salute them. As the Americans passed by those "Greeks" called out in excellent English

"How is America?"

"What news from Broadway?"

"Will be back soon!"

They were "reservists" who were working in America when the war broke out, and were called home to serve in the army. This mixing-up process has been going on all over Europe, and it is like the leaven in the loaf. Men began to see that they were not born to be machines or cogs in a great, cruel military system, but that they have certain human rights. They are still kept down with an iron hand, and the trouble is that for centuries they have been bred and trained to do what they are told, and never think. It is part of an autocratic government from the ruling of a great nation down to the petty political bossing for the masses to work and for the ruler to do their thinking for them. When after years of such training an, breeding the common people really try to do their own thinking, of course it is clumsy and often childish or narrow. It means growth, however, and beneath the iron rule of the monarchies, Europe is growing into self-government.

THE WAR.—All these things and many more have helped start this war. For years they have all been simmering away, but not until a half-crazy student shot down the Austrian prince and his wife did they all flare up together. That tragedy fanned the religious feeling into a flame. Austria was forced by this excitement to make demands on Servia. Both Germany and Austria are honeycombed with intellectual revolt—that is what I have called the "manhood" issue—a fairer chance for the common people. If you will read that old essay in Germany by Tacitus, you will see that the German people have always been noted for their strong, blind, unwavering devotion for the "Fatherland." A war, or an appeal to patriotism, is the last resort of a strong military government, and both Austria and Germany had come to the point where such an appeal was needed to stop people from thinking for themselves. The moment the flame was started by that student's pistol in Servia it found Europe like a tinder-box all ready for a blaze. France saw her only chance of regaining her lost provinces. Belgium saw her national integrity going. England saw her sea power menaced and treaty obligations in danger. Russia saw her chance to gain territory and keep her subjects satisfied, the Balkan States and Greece saw their chance to strike at an old enemy, and even Japan in the Far East, saw that she might, perhaps, put England under obligation to her. So all of a sudden the fighting began. They had all prepared for it, for they knew it was coming. It had to come, as we see when we look over the things which have led up to it. Now it will probably be fought out to a finish, and not even the wisest student of history will attempt to say what that finish will be. The questions involved do not touch this country except that a good proportion of our people come from Europe and have brought some of their race feelings and national devotion with them. We should keep out of it.

FARM PROSPECTS.—While Europe has been plunged into war, the American farmer is engaged in the peaceful occupation of harvesting his earlier crops and cleaning up his late ones. This is not always as peaceful as the poet would have us believe. Bug and blight, drought or wet, and may put up a good battle. The middle of August finds us picking the Carman peaches and the early apples, beginning to seed the cover crops, potting strawberry plants and thinning the beets. There is plenty of work. There is a fair peach crop. The Carmans are brick red on the sunny side, and of fine flavor. There is a good local demand for them. The early apples have been slow of sale. No sale at all for the sweets. Our potato crop is the best we have ever had, and the corn looks well. The late apples promise a great crop, but we all understand that they must be handled with great care this year to get anything like a fair price. On the whole, our season promises to be a good one.

Cut a clean smooth thread on that old battered bolt in 2 minutes

Don't lose the time to go to the blacksmith shop. Don't keep your team and hired hands idle. Don't let your work suffer.

Think how many bolts there are in your farm machinery and auto. Think how easy a thread gets battered-up so the nut won't go on.

Be ready for emergencies. Be ready to save time and money by getting at once a set of

Little Giant

Hexagon Dies

This set takes care of any size bolt from ¼" to ¾". All you need is a monkey wrench or pliers to turn the die. Two minutes does the trick and one thread recut may save you twice the price of the set.

The man who makes money at the end of the year is the man with the foresight. Get a set of Little Giant Hexagon Dies for your tool bench at once.

Send $5 for set of 8 dies, ¼"—5/16"—⅜"—7/16"—½"—9/16"—⅝"—¾".

Sent prepaid parcels post. Your money refunded if in any way unsatisfactory.

GREENFIELD TAP & DIE CORP.

Quick Delivery Over Long Distances

80-Mile Daily Runs Prove Value of *Autocar* to Wyncote Concern

LITTLE conception of the immense area the *Autocar* will cover is held by the average man who sticks to old methods of delivery and hauling.

A first-class pair of horses, if the roads are good, can travel 20 to 30 miles in a day with a loaded wagon, but the next day has to be laid off to rest up. An *Autocar* covers 50 miles a day without exerting itself and fully two-thirds of our customers run their cars 70 to 80 miles day by day and 90 to 100 miles in emergencies.

Joseph Heacock & Company, of Wyncote, Pa., recently gave us the following information about the work of their *Autocar:*

" We have greenhouses at Wyncote and a dairy and rose-growing industry at Roelofs, Pa. Every day, both week days and Sundays, our *Autocar* starts out about 5 o'clock in the morning for Roelofs and takes on a load of milk which it carries to Philadelphia. Then it comes back to Wyncote, arriving about noon, completing a route of 60 miles. In the afternoon, the car loads up with plants for Philadelphia or elsewhere and averages 20 to 30 miles on its afternoon trips, thus traveling in all 80 to 90 miles a day.

"Formerly, we carried our milk from Roelofs to Philadelphia by train. The *Autocar* service is a great improvement over this as the milk requires less handling and we can depend on its arriving more promptly."

The Autocar

"Used in Every Line of Business"

There are more than 1,700 *Autocar* owners many of them possessing from 10 to 270 *Autocars* each. Write today for the new *Autocar* book and information concerning the *Autocar* on the farm. Address Dep't R

Pot Bulbs in the House.

WE are well supplied with outdoor flowers now; French and African marigolds, Calendulas, Zinnias, Phlox and Dahlias are plentiful enough for lavish cutting, but it is time to prepare for the lean months when outside flowers are gone. We find nothing more satisfactory for Winter flowers than bulbs in pots, which provide us with bloom from the end of November until the first Siberian squills and Glory-of-the-snow appear out of doors. The cost is not large, the most expensive bulbs we buy being a few extra choice hyacinths, costing in Holland from 10 to 18 cents each.

THE SOIL for all forcing bulbs should be rich loam. Fresh manure should never be used; a little bone meal may be added to advantage. If the soil is a stiff clay some sand and leaf mold should be worked in. Abundant drainage should be given in the form of broken crocks, stones or bits of charcoal in the bottom of the pots. When the soil is put in the pots it must be shaken down, but not packed hard, or the roots will often raise the bulb out of the pot. After the potting is finished the soil should be a full half inch below the brim of the pot, so as to allow room for watering. Plant the bulb just deep enough so that its top will not show. After potting the bulbs are watered moderately and then stored away to make roots in a cool dark place. An unheated cellar is good; so is a pit or cold frame, or even a dark woodshed, so long as they do not freeze, and are not allowed to dry out. A suitable temperature range is 40 degrees for roots, 50 for foliage, and 60 degrees for developing bloom.

STARTING GROWTH.—When freezing weather begins the bulbs are removed from their cold starting place to the house cellar, where they remain in the dark, watered at intervals, with some sacking thrown over them to prevent rapid drying out. They are filling their pots with strong roots, but by and by top growth begins, and they are then brought to the light, in a cool room, and grown on until the flower spikes push out, when they are brought into the living room. Sometimes the flower spike is very slow in making height, and seems disposed to open its flowers while still very short. This can be remedied by making a tube of stiff paper and setting over the plant for a few days; it naturally draws up to reach the light, and a day or two of this treatment makes a surprising change in growth. One may begin potting bulbs by the middle of September, thus providing for a succession, especially in Roman hyacinths, but the majority are potted from the first to the middle of October.

ROMAN HYACINTHS.—First to bloom, and quite indispensable, are the Roman hyacinths; these are small, but usually produce several spikes to the bulb, and we expect to have them in flower at Thanksgiving. These are usually set one bulb in a four-inch pot, but are also very attractive when several are set in a flat bulb pan. If a number are planted they can be brought on by degrees, holding some back in the lower temperature. "Romans" may be purchased in three colors, blue, rose and white, but we only grow the white.

DUTCH HYACINTHS.—We advise first size bulbs of these, for the big specimen spikes are worth the small extra price. The second size are quite satisfactory for bedding out. Among the earliest sorts are L'Innocence, white, General Pelissier, dark red, Lady Derby, rose, and Schotel, pale blue. Other excellent single sorts are Czar Peter, light blue, Lord Derby, light blue, La Grandesse, the finest white, Charles Dickens, dark purplish blue, Cardinal Wiseman, deep rose, Lord Macaulay, rose and flesh stripes, King of the Yellows, pure yellow. The double hyacinths are very fine, but under house conditions not quite as satisfactory as the singles, though we get some very fine spikes. Garrick, deep lilac blue, Lord Nelson, pale blue, very fine, La Tour d'Auvergne, pure white, very early, Leo, pale carmine, Bloksberg, pale blue, and Othello, very dark blue, are all good double varieties. There are also miniature Dutch hyacinths, strong and sturdy, but making spikes only about six or seven inches high; they are very attractive planted in pans.

TULIPS.—We do not expect our tulips to blooom till after the holidays; the earliest of all are Duc Van Thol and Pottebakker which give us several colors, and are of great value to florists, and for bedding, because of their earliness and the ease with which they are forced. But for use in the house we prefer some others, whose flowers we like better. Among these in single sorts are Cottage Maid, pink and white, one of the most satisfactory for commercial forcing; Bacchus, deep red, and Artis, bright scarlet; Joost von Vondel, deep crimson penciled white; Proserpine, deep rose; Rose Grisdelin, dwarf, rose and white; Vermilion Brilliant, bright scarlet; Belle Alliance, scarlet; Cramoisi Brilliant, very fine, vivid red; Couleur Cardinal, orange scarlet shading outside to purple, late; Chrysolora, yellow, very good. Double tulips that force well are Couronne d' Or, yellow; Gloria Solis, brown and yellow; Murillo, rose and white very fine; Tournesol, red and yellow; Salvator Rosa, dark rose and white.

PARROT OR DRAGON TULIPS.— These always excite admiration, because of their crimped and slashed petals, and strangely streaked and flamed coloring. They are admirable for house forcing, because they must be brought out slowly, without strong heat. They come into bloom late. The following varieties have given us good results Café Brun, deep yellow feathered with red; Lutea Major, yellow; Markgraaf von Baden, golden orange striped scarlet, very large.

OTHER FORCING BULBS.—Many varieties of Narcissus are excellent for pot culture in the house. The Chinese Sacred lily is usually grown in water, but it does very well in soil, while the familiar Paper White so much forced commercially is very easily grown. Van Sion is the standard yellow forcing daffodil but most of the trumpet sorts are good. The little Crocuses are charming set in a flat pan, but they must not be hurried in any way. Allium Neapolitanum, though a near relation of the savory onion, is excellent for forcing. Freesias are very easily flowered in the house. The whole theory of bulb forcing is to get a strong growth of roots before the top starts, and this makes their culture especially easy and satisfactory for the amateur.

No War Prices

On Goodyear Tires. All advances—due to doubled cost of rubber—were withdrawn on August 19th. This applies to dealers and consumers.

We have secured from abroad sufficient rubber at former prices to warrant this announcement. Goodyear prices are now everywhere the same as they were before the war.

Sturdier Tires

In These Four Ways Excelling All the Rest

The tires which rule in Tiredom now are Goodyear tires—by long odds.

After men have used four millions of them, they lead in prestige and in sales.

The only reason is that motorists—hundreds of thousands of them—have proved these the sturdiest tires. They use them and tell other men to use them.

Where They Excel

Back of that super-service lie four exclusive features. They are these:

Our No-Rim-Cut feature. Time has proved it the only satisfactory way to completely wipe out rim-cutting.

Our "On-Air" cure. This exclusive process costs us $1,500 daily, but it ends the chief cause of blow-outs.

Our rubber rivets. By a patent method, hundreds of these are formed in each tire to combat tread separation. They reduce this risk sixty per cent.

All-Weather treads—the matchless anti-skids. They are tough, double-thick and enduring. Resistless on wet roads with their deep, sharp grips; yet flat and smooth, so they run like a plain tread.

Upper Class Tires How to Get Them

These things make Goodyears the upper class tires. No other maker employs them. And no other method combats one of these troubles in an equally efficient way.

These things mean safety, sturdiness and strength. They mean maximum mileage and minimum trouble.

When one tire gives them—and others don't—you should get the tire that does.

Any dealer will supply you if you say you want this tire. He will sell it to you at a price impossible were it not for our mammoth output.

It is up to you. Note again these extra features. Then ask some Goodyear user what it means to have such tires.

Find out why Goodyear leads.

THE BUSINESS FARMER'S PAPER

A National Weekly Journal for Country and Suburban Homes

Established 1850

Published weekly by the Rural Publishing Company, 333 West 30th Street, New York
HERBERT W. COLLINGWOOD, President and Editor.
JOHN J. DILLON, Treasurer and General Manager.
WM. F. DILLON, Secretary. MRS. E. T. ROYLE, Associate Editor.

SUBSCRIPTION: ONE DOLLAR A YEAR

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs. Remit in money order, express order, personal check or bank draft.

Entered at New York Post Office as Second Class Matter.

Advertising rates, 75 cents per agate line—7 words. References required for advertisers unknown to us; and cash must accompany transient orders.

"A SQUARE DEAL"

We believe that every advertisement in this paper is backed by a responsible person. We use every possible precaution and admit the advertising of reliable houses only. But to make doubly sure, we will make good any loss to paid subscribers sustained by trusting any deliberate swindler, irresponsible advertisers or misleading advertisements in our columns, and any such swindler will be publicly exposed. We are also often called upon to adjust differences or mistakes between our subscribers and honest, responsible houses, whether advertisers or not. We willingly use our good offices to this end, but such cases should not be confused with dishonest transactions. We protect subscribers against rogues, but we will not be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent to us within one month of the time of the transaction, and to identify it, you should mention THE RURAL NEW-YORKER when writing the advertiser.

OUR advice to farmers north of New York City has been to sow Hairy vetch before September 1. We now have letters from people as far north as Syracuse asking if it will be safe to seed the vetch as late as October? No, we would not advise it. Rye alone would be safer.

*

IN parts of New York peddlers are now going about with bulk shipment apples. The wagons are built high with side boards, and the apples dumped in like a farmer going to cider mill. This fruit was shipped here in box cars and sold for what it would bring. It is peddled at a low price so that thousands are eating apples who otherwise would not touch them. This works both ways. It hurts the sale of barreled stock while the rush lasts, but it is the greatest advertisement for apple eating that could be thought of.
